Technical Support

Technical Support maintains support centers globally. All support services will be delivered in accordance with your support agreement and the then-current enterprise technical support policies. For information about our support offerings and how to contact Technical Support, visit our website:

https://www.veritas.com/support

You can manage your Veritas account information at the following URL:

https://my.veritas.com

If you have questions regarding an existing support agreement, please email the support agreement administration team for your region as follows:

Worldwide (except Japan)

CustomerCare@veritas.com

Japan

CustomerCare_Japan@veritas.com

Documentation

The latest documentation is available on the Veritas website:

https://sort.veritas.com/documents

Documentation feedback

Your feedback is important to us. Suggest improvements or report errors or omissions to the documentation. Include the document title, document version, chapter title, and section title of the text on which you are reporting. Send feedback to:

NB.docs@veritas.com

You can also see documentation information or ask a question on the Veritas community site:

Veritas Services and Operations Readiness Tools (SORT)

Veritas Services and Operations Readiness Tools (SORT) is a website that provides information and tools to automate and simplify certain time-consuming administrative tasks. Depending on the product, SORT helps you prepare for installations and upgrades, identify risks in your datacenters, and improve operational efficiency. To see what services and tools SORT provides for your product, see the data sheet:

https://sort.veritas.com/data/support/SORT_Data_Sheet.pdf

Chapter

NetBackup licensing models and the nbdeployutil utility

This chapter includes the following topics:

- Methods to gather and analyze licensing reporting
- About NetBackup licensing models
- nbdeployutil utility options
- Creating and viewing the licensing report
- After creating a traditional licensing report
- After creating a capacity licensing report
- Reconciling the capacity licensing report results

Methods to gather and analyze licensing reporting

NetBackup provides multiple methods to gather and analyze licensing reporting.

ΤοοΙ	Description	Run options
nbdeployutil command	The nbdeployutil command provides command-line access to data or capacity usage and business unit reporting. The command generates a Microsoft Excel spreadsheet to review. The master server must have a utility for reading .xls files.	For traditional reporting: The nbdeployutil command must be run manually. For capacity reporting: The nbdeployutil command can be run manually or per incremental schedule.
NetBackup OpsCenter	OpsCenter provides an interface useful for multi-server environments.	Run manually in OpsCenter.

Table 1-1 Reporting tools for licensing and run options

About NetBackup licensing models

NetBackup uses two licensing models:

- The traditional licensing model counts the number of clients and servers, and then compares this information against licensed options.
 See "About the traditional licensing model" on page 11.
- The capacity licensing model calculates how much data at source is protected.
 See "About the capacity licensing model" on page 11.

About the traditional licensing model

The traditional licensing model is based on the total number of protected clients in a NetBackup environment or on the total storage capacity.

About the capacity licensing model

Capacity licensing is based on the total amount of data that NetBackup protects on the client or agent. When the capacity licensing model is used, NetBackup automatically gathers the information in one of two methods:

- By getting the information from the backup image header. If a policy type is not yet supported for the accurate licensing method, this method is used.
- By using the accurate licensing method.

NetBackup automatically uses this method if the policy type supports accurate licensing. Each supported policy type uses a unique mechanism at backup time

to calculate the size of the data that the policy is protecting. This information is gathered and then stored in the NetBackup database.

The following policy types report data size using accurate licensing:

MS-Windows

See "File Systems (Windows and UNIX backups)" on page 23.

- Standard See "File Systems (Windows and UNIX backups)" on page 23.
- MS-Exchange-Server
 See "NetBackup for Exchange Agent" on page 14.
- MS-SQL-Server
 See "NetBackup for SQL Server Agent" on page 15.
- VMware See "NetBackup for VMware Agent" on page 18.
- NDMP

See "NetBackup for NDMP Agent" on page 20.

- Oracle
 See "NetBackup for Oracle server agent" on page 17.
- BigData

See "BigData plug-ins for NetBackup" on page 25.

Accurate licensing enables the user to have the following:

- Faster performance of the nbdeployutil tool to gather and generate capacity licensing report as NetBackup stores the front-end size of backup data.
- Precise Front-end Terabytes (FETBs). If multiple backup copies are created, only the first copy is considered.

NetBackup client version	Supported policy types
8.0	MS-Windows, Standard, MS-Exchange-Server, MS-SQL-Server
8.1	MS-Windows, Standard, MS-Exchange-Server, MS-SQL-Server, VMware, NDMP, Oracle, BigData (for Hadoop HDFS and Nutanix Acropolis Hypervisor)

The capacity licensing report includes details about the mechanism that is used based on the policy type. nbdeployutil securely communicates with the master

server to gather the protected data sizes and generate reports. The report is generated only for full backups and user-directed backups (including expired backups) for the last 90 days per the license agreement.

All of the clients included in the policy must be updated to NetBackup 8.1 or later when accurate licensing is used. The reporting data for any clients that run older NetBackup versions is not included in the calculation of protected data. For these clients, the capacity licensing numbers are generated using the legacy method of backup image header.

The data size that is reported in the Itemization sheet of the report under **Storage Types**, for example, Tape, BasicDisk, PureDisk, etc., is the front-end data size that is backed up to that specific storage type and not the storage size that the backup consumes.

About multiple policies that protect data

Users are charged based on the protected data size. If multiple backup copies are created using a single policy (a copy created and stored on disk, for example), only the first copy is considered for calculation. The other copies are not charged to the user.

If multiple policies of the same type protect the same data, the capacity report identifies the overlap. The user needs to calculate the actual data overlap and then configure the policies considering this overlap. The user can then change the report based on the overlap. The overlap is only applicable to data reported using accurate licensing.

To record protected data, an agent must have a valid certificate (issued by the master server) to securely connect with the master server. If the certificate is not generated and available on the client, the protected data is not recorded using accurate licensing. In this scenario, the data is reported using the backup image header in the capacity licensing report. After the certificate is available and protected data is recorded using accurate licensing, the method of using the backup image header is no longer used.

The user can generate the certificate by using the nbcertcmd command. For more information about this command, refer to the *NetBackup Commands Reference Guide*.

See "Generating licensing reports manually" on page 32.

How capacity licensing uses Front-end Terabytes

The licensing fees for the use of NetBackup are based on the total number of Front-End Terabytes (FETBs) protected by NetBackup. Front-End Terabyte Calculation is a way of determining the total terabytes of data NetBackup protects. One FETB is 1 TB of protected data. The data can either be on clients or devices

where the software is installed or where the software is used to provide backup functionality.

The nbdeployutil utility uses accurate licensing or image headers in the NetBackup catalog to determine the terabytes of data that NetBackup protects. Any partial terabyte of data is rounded up to the next whole terabyte. The final total is the sum of the FETBs for each client or policy combination that the analyzer examines. The utility measures the actual data protected.

NetBackup for Exchange Agent

The NetBackup for Exchange Agent reports data using the accurate licensing method when capacity licensing is used. After a backup is complete using the **MS-Exchange-Server** policy type, the agent captures the size of data that the policy protects. The data is reported to the master server.

Using the **MS-Exchange-Server** policy, as the Exchange database is backed up; the definition of protected data for the policy is the size of Exchange database (.edb file). Licensing for Exchange is specific to an **MS-Exchange-Server** policy and does not support an Exchange server that is backed up using any virtualization policy, such as **VMware**.

Exchange 2007 snapshot based backups are supported similar to Exchange 2010, 2013, and 2016.

Note: Licensing for Exchange does not support Exchange 2007 streaming backup policies. For these policies, the report is generated using the existing method of capacity licensing (backup image headers).

Administrators can use any of the following ways to verify if the Exchange database size that is reported by the accurate licensing method is correct.

 Use the Microsoft Exchange Management shell command that is available by default on the Exchange server.

Get-MailboxDatabase -Status | select Name, DatabaseSize Use the help Get-MailboxDatabase command to see more information about this command.

 Check the properties of Exchange database file (.edb) that was backed up on the Exchange server to view the size of the file.

Database Availability Group (DAG)/Cluster backups	Standalone exchange backups
In an Exchange DAG/Cluster environment, a user can choose a DAG directive to back up all Exchange databases or back up an individual database of DAG as a standalone database backup.	For a standalone Exchange environment, protected data is reported. For multiple policies with some common databases, overlap is
Overlap is reported for DAG. You can back up an Exchange DAG database from any node based on the server preference list that is configured in the backup policy. No matter which node is used to back up the Exchange DAG database, the capacity licensing report identifies the database uniquely across DAG nodes, and identifies overlap. The protected data size is calculated from the node that is used to backup the Exchange DAG database.	identified.

Table 1-3Reporting for Exchange backup environments

NetBackup for SQL Server Agent

The NetBackup for SQL Agent automatically uses the accurate licensing method when capacity licensing is used. After a backup is complete using the **MS-SQL-Server** policy type, the agent captures the size of data that the policy protects. The data is reported to the master server.

Licensing for SQL is specific to the **MS-SQL-Server** policy type. NetBackup collects the data for any SQL backup that can be restored, not including transaction logs. The backup selection is defined in the **SQL Instances and Databases** tab in the policy.

The following SQL queries are used to gather file size information.

Get size of entire database

Given the database name, this query gets the file size in MB, not including the transaction log:

```
USE <dbname>;
SELECT CAST(SUM(dbfile.size) AS FLOAT) / 128.0 AS FileSizeInMB
FROM sys.database_files AS dbfile
WHERE dbfile.drop_lsn IS NULL
AND dbfile.type <> 1;
```

Get size of entire database for skip read-only file groups option

Given the database name, this query gets the file size in MB for skip ReadOnly file groups option:

```
USE <database_name>;
SELECT
sysFG.name AS FileGroupName,
SUM(CAST(dbfile.size AS float) / CAST(128 AS float)) AS FileSizeInMB
FROM
sys.database_files AS dbfile
INNER JOIN
sys.filegroups AS sysFG
ON
dbfile.data_space_id = sysFG.data_space_id
WHERE
sysFG.is_read_only = 0 and drop_lsn is null
GROUP BY
sysFG.name;
```

Get the size of file groups for a partial backup

Given the database name, this query gets the file size in MB for file groups that are specified in the partial list:

```
USE <database_name>;
SELECT
sysFG.name AS FileGroupName,
SUM(CAST(dbfile.size AS float) / 128.0) AS FileSizeInMB
FROM
sys.database_files AS dbfile
INNER JOIN
sys.filegroups AS sysFG
ON
dbfile.data_space_id = sysFG.data_space_id
WHERE
drop_lsn is null
and sysFG.name in (<delimited fg name>, ...)
GROUP BY
sysFG.name;
```

Get size of file and corresponding file group name

Given the file name (object name) and database name, this query gets the file size in MB and the corresponding file group name:

```
USE <database name>;
SELECT
sysFG.name AS FileGroupName,
(CAST(dbfile.size AS float) / 128.0) AS FileSizeInMB
```

```
FROM
sys.database_files AS dbfile
INNER JOIN
sys.filegroups AS sysFG
ON
dbfile.data_space_id = sysFG.data_space_id
WHERE
dbfile.name = N'<file name>' and drop lsn is null
```

Get size of file group

Given the file name (object name) and database name, this query gets the file group size in MB:

```
USE <database name>;
SELECT
SUM(CAST(dbfile.size AS float) / 128.0) AS FileSizeInMB
FROM
sys.database_files AS dbfile
INNER JOIN
sys.filegroups AS sysFG
ON
dbfile.data_space_id = sysFG.data_space_id
WHERE
sysFG.name = N'<filegroup name>' and drop lsn is null
```

NetBackup for Oracle server agent

The NetBackup Oracle agent automatically uses the accurate licensing model when capacity licensing is used. After a backup is complete using the Oracle policy type, the NetBackup for Oracle agent captures the size of data that the policy protects. This data is reported to the master server. The size of the data that is reported does not include the NetBackup for Oracle XML Archiver.

Accurate licensing for Oracle is specific to an Oracle policy. This type of licensing collects the front-end data size (FEDS) for any Oracle backup that can be restored, not including transaction logs. The backup selection is defined in the Oracle Instances and Databases tabs in the policy (OIP, templates, and scripts). The data size collection may not work properly if OS authentication is disabled.

The following Oracle queries are used to gather file size information.

Get size of database files being backed up

Given the database file name(s) that are backed up, these queries retrieve the file size (in MB) for every database in an instance. These queries do not include the transaction log:

select name, BYTES/1024/1024 from v\$datafile; (where name is the name of the database file being protected in the backup policy) Or to collect the entire sum of the database files in the instance, use the following query:

select sum(BYTES/1024/1024) from v\$datafile;

Get the size of the control file

Given the database name, this query gets the control file size (size is only collected for one) in MB, not including transaction log:

```
select name, BLOCK_SIZE*FILE_SIZE_BLKS/1024/1024 controlfile_size
from v$controlfile;
```

NetBackup for VMware Agent

The NetBackup for VMware agent reports data using accurate licensing. After a backup is complete using the **VMware** policy type, the agent captures the size of data that the policy protects. The data is reported to the master server.

Accurate licensing for virtual machine (VM) is specific to a VMware policy. This type of licensing collects the total number of Front-End Terabytes (FETBs) protected by NetBackup.

The following list contains all the selections in the **Exclude Disks** tab of the VMware policy type. The options are used to exclude certain virtual disks from virtual machine backup.

- No disks excluded: This type of backup includes data in all disks of a virtual machine.
- Exclude boot disk: This type of backup includes all data that is not on the boot disk of a virtual machine.
- Exclude all data disks: This type of backup only includes data in the boot disk of a virtual machine.
- Perform custom attribute based exclusion: This type of backup includes all data that is not on the custom attribute defined on the virtual server.
- Specific disks to be excluded: This types of backup includes all data that is
 not on the selected disk controllers. You can add multiple disk controllers in the
 exclusion list by the connection type and controller ID.

The nbdeployutil utility reports actual data usage by calculating the accurate data size using the related backup files and policies. The following rules are executed to guarantee data size accuracy:

- If the data size backed up by the policy Include all disks is greater than the sum of other two policies, the data size of Include all disks is counted.
- If the data size backed up by the policies Exclude data disks and Exclude boot disk are greater than the Include all disks, the data size of Exclude data disks and Exclude boot disk is counted.
- If identical policies are taken, the policy with higher size is counted.
 If different policies use the same virtual machine (VM) identifiers, they are detected as identical policies.

The primary VM identifiers include:

- VM hostname
- VM display name
- VM BIOS UUID
- VM DNS Name
- VM instance UUID

The uncounted policies are displayed with 0 data size in the FEDS table generated by the nbdeployutil utility.

System administrators can use the following ways to verify the correctness of the data size reported by accurate licensing.

To verify the correctness of data size reported by accurate licensing

- If all disks are included in the backup, verify size on ESX datastore.
- If a specific disk is excluded during the backup, verify the size by logging on to the guest operating system (OS) of the virtual machine and use commands to get the size of selected disk.

When backup agent fails to post licensing information to database, one of following error messages is displayed in the activity monitor:

WRN: Posting to feds failed. status: 5930

The message indicates that the backup agent encountered an authorization issue, with a certificate expired or nbwebsvc account password expired.

WRN: Posting to feds failed. status: 26

The message indicates backup agent encountered a service offline issue, with the service NetBackup web console not running.

For more information, see the Veritas NetBackup Status Codes Reference Guide.

NetBackup for NDMP Agent

The NetBackup for Network Data Management Protocol (NDMP) Agent reports data using the accurate licensing method when capacity licensing is used. After backup is complete using the **NDMP** policy for Network Attached Systems (NAS), the **NDMP Agent** captures the size of data that the policy protects. The data is reported to the master server.

Accurate licensing for NDMP is specific to an **NDMP** policy type. This type of licensing collects the front-end data size (FEDS) based on the backup selections that are defined in the **NDMP** backup policy types.

Following are some of directives, wildcard characters, and path names that are available as backup selections in NDMP workload.

Directives

ALL_FILESYSTEMS

The ALL_FILESYSTEMS directive provides a method to include all file systems and volumes on an NDMP filer in an NDMP backup policy. You can exclude specific volumes from an ALL_FILESYSTEMS backup selection if you do not want to back up every volume on an NDMP filer. Use the VOLUME_EXCLUDE_LIST directive for this purpose.

NEW_STREAM

The **NEW_STREAM** directive is used when **Allow multiple data streams** is enabled otherwise it is ignored. In this mode, following can occur:

- The backup splits into separate stream in backup selections wherever NEW_STREAM directive occurs.
- All file paths between **NEW_STREAM** directives belong to the same stream.
- Start of NEW_STREAM defines the end of previous stream.
- The last stream in the backup selection list is terminated by the end of backup selection list.

Wildcard character

• *

Regular expression containing the wildcard character * is used to match the NDMP backup selection for all volumes or folders present on the **NDMP** filer. However, regular expression matching cannot be used for files and is not supported for NDMP workload.

If a filer has three volumes /VolumeA, /VolumeABC and /VolumeDEF and each volume having folders with names prefix as Folder, then the following selections are valid:

- /Volume* matches all the volumes prefixed with Volume that present on the NDMP filer
- /VolumeA/Folder* matches all the folders prefixed with Folder in VolumeA that present on the NDMP Filer
- ∎ ?

Regular expression containing the wildcard character **?** is used to match the NDMP backup selection for all volumes or folders present on the **NDMP** filer. However, regular expression matching cannot be used for files and is not supported for **NDMP** workload.

If a filer has three volumes /VolumeA, /VolumeB and /VolumeC and each volume have three folders Folder1, Folder2, and Folder3, then the following selections are valid:

- /Volume? matches all the volumes present on the NDMP Filer with prefix as volume and having any single character after that.
- /VolumeA/Folder? matches all the folders having prefix as Folder in VolumeA and having any single character after that.
- [...]

Regular expression containing the wildcard character [...] is used to match the **NDMP** backup selection for alphanumeric pattern match. Regular expression containing the wildcard [...] cannot be used for files and is not supported for **NDMP** workload.

- /fs[1-9] matches all paths that begin with the literal characters /fs and end with any single numeric character from 1 through 9.
 For example, /fs1, /fs2, and so on up to /fs9 match the specified pattern /fs[1-9]. However, /fs0 and /fsa do not match the specified pattern.
- /vol/ndmp[0-9] matches any volume name that begins with /vol/ndmp and ends with a single numeric character 0 through 9.
- /vol/ndmp[0-9][0-9] matches any volume name that begins with /vol/ndmp and ends with the two-digit numeric characters 00 through 99.
- /vol/ndmp[0-9][0-9][0-9] matches any volume name that begins with /vol/ndmp and ends with the three-digit numeric characters 000 through 999.

Pathname

- /volumeA matches all the files or folders in the VolumeA that present on the NDMP filer.
- /volume/FolderA matches all the files in the folderA that present on the NDMP filer.

 /volume/FolderA/FileA matches the file FileA only that presents on the NDMP filer.

The **NBDeployUtil** reports actual data usage without overlap by calculating the accurate data size using the related backup files and policies. Following rules are applied to guarantee data size accuracy:

- If the data size backed up by a policy with ALL_FILESYSTEMS directive is greater than the sum of other policies, the data size of ALL_FILESYSTEMS directive is counted.
- If identical policies are taken, then the policy with higher size is counted.
- The uncounted policies are displayed with 0 data size in the NBDeployUtil report.
- If data size backed up by policy P1 is consumed in another policy P2, then the data size of policy P2 only is counted.
- If data size is overlapped in multiple policies, then it is counted only once.

System administrators can use the following ways to verify the correctness of the data size reported by accurate licensing.

To verify the size of volumes with **NetApp ONTAP 9** filer, log on to **NetApp ONTAP** filer and run the following command:

volume show -fields size, used, available, percent-used.

Alternatively, administrator can mount the volume of **NDMP** filer (Provided NFS protocol is enabled for that Volume) on any Linux/Unix based client and execute the following commands:

o du -sh o ls -lh

When backup agent fails to post licensing information to database, one of the following error messages is displayed in the activity monitor:

WRN: Posting to feds failed. Status: 5930

The message indicates that the backup agent is encountered an authorization issue, with a certificate expired or **nbwebsvc** account password expired.

WRN: Posting to feds failed. Status: 26

The message indicates that the backup agent is encountered a service offline issue, with the service NetBackup web console not running. For more information, see the *Veritas NetBackup Status Codes Reference Guide*.

File Systems (Windows and UNIX backups)

NetBackup automatically uses the accurate licensing method for Windows and UNIX files systems when capacity licensing is used. After a backup is complete using the **MS-Windows** and **Standard** policy types, the agent captures the size of data that the policy protects. The data is reported to the master server.

Windows backups

Licensing for the Windows backup is specific to an **MS-Windows** policy and does not support the Windows clients or servers that are backed up using any virtualization policy, such as **VMware** and **HyperV**.

Using the **MS-Windows** policy, the Windows data is backed up based on the pathname or directive that is defined in the policy. The definition of protected data is the size of the directives and pathnames for the policy.

Directives:

ALL_LOCAL_DRIVES

NetBackup posts all data in this directive. Run the file system commands, calculate size of each drive, and compare the size that is reported in the capacity licensing report. The files that are mentioned in the exclude list are not used to calculate protected data.

System State

Only System State data is backed up. NetBackup creates the xml files of backup data under logs\BEDS folder and lists the files that are backed up and excluded from backup. System state backup is needed for the operating systems that do not support Shadow Copy.

Shadow Copy Components

System State data is backed up. NetBackup creates the xml files of backup data under $logs\BEDS$ folder and lists the files that are backed up and excluded from backup.

ADAM

Active Directory Application Mode (ADAM) is a lightweight directory service that runs as a user service. This directive is used to back up ADAM data on computers where it is installed.

NEW_STREAM

Multiple data streams are backed up.

Pathname:

Specific drives

Backs up only the data on the file system drive. NetBackup does not back up System State data and excludes file data.

Folders and files

Backs up the files and folders that are specified in the backup selection. Run the file system command and compare the size that is reported in the capacity licensing report.

Snapshot-based backups are supported on all the versions of Windows servers and clients with various features of NetBackup such as multistreaming, Accelerator, compression, and so on.

Administrators can run commands to verify the size that the accurate licensing method reports. The following commands are available by default on Windows.

∎ Dir

Lists the files on the system folders and their sizes.

Get-ChildItem C:\test1 | Measure-Object -property length -sum
 PowerShell command to get folder size.

Users can also view size information from Windows Explorer. Right-click the drive, file, or folder, and then click **Properties**.

UNIX backups

Licensing for UNIX is specific to **Standard** policy type and does not support UNIX clients or the servers that are backed up using any virtualization policy, such as **VMware**.

Using the **Standard** policy, the UNIX file system data is backed up for the directive or the backup selection that is defined in the policy. The definition of protected data for the policy is the size of ALL_LOCAL_DRIVE or specific mount points\partitions or files.

Specific mount points\partition or files

Backs up the files and folders that are specified in the backup selection. Run the file system command and compare the size that is reported in the capacity licensing report.

ALL_LOCAL_DRIVE

NetBackup posts all data under ALL_LOCAL_DRIVE backup directive. Run the file system commands, calculate the size of each mount point\partition, and compare the size that is reported by the capacity licensing report. The files that are mentioned in the exclude list are not included in the calculation.

The snapshot based backups are supported on all the versions of UNIX Server and clients with various features of the NetBackup such as multistreaming, Accelerator, compression, and so on.

Administrators can run UNIX commands to verify the size reported by the accurate licensing method. The following UNIX are available by default:

- ∎ df -l
- ∎ ls -lh

For more information on pathnames and directives and mount points and partitions, see the *Veritas NetBackup Administrator's Guide, Volume I*.

For more information on supported Windows and UNIX file systems, see the *NetBackup Software Compatibility List*:

http://www.netbackup.com/compatibility

BigData plug-ins for NetBackup

The **BigData** plug-ins for NetBackup report data using the accurate licensing method when capacity licensing is used. After a backup is complete using the **BigData** policy type, the plug-ins capture the size of data that the policy protects and report this information to the master server.

Capacity licensing collects front-end data size for all the full backups that can be restored and are taken using the **BigData** policy for the following plug-ins:

- Hadoop plug-in for NetBackup
- Nutanix plug-in for NetBackup

After the nbdeployutil utility runs using the capacity licensing option, the report displays the policy type in the **Itemization** sheet as follows:

- BigData:hadoop
- BigData:Nutanix-AHV

Hadoop plug-in for NetBackup

Using the **BigData** policy, the Hadoop (HDFS) data is backed up for the directory or the backup selection that is defined in the policy. The definition of protected data for the policy is the size of the defined directories that have the allow snapshot option enabled on an HDFS file system. To view the defined directory size, you can browse the file system using the Hadoop web console.

Administrators can also run the following HDFS command to verify the size that capacity licensing reports. The following HDFS commands are available by default:

hdfs dfs -ls -R -h /<name_of_the_directory>

Nutanix plug-in for NetBackup

The front-end data size that is reported for Nutanix Acropolis Hypervisor is the consumed storage size. You can verify the consumed storage size on the Nutanix AHV console by navigating to **VM > Overview > Tables** under the **Storage** column.

The Storage column displays the consumed storage size as compared to the total allocated storage size.

nbdeployutil utility options

The nbdeployutil utility is used to gather data and analyze licensing data, and then present the results in a spreadsheet as a report. The utility can be used to report on both the traditional or the capacity licensing model. The utility can be run automatically according to a customizable incremental schedule (for capacity reports only) or manually (for traditional and capacity reports).

Incremental capacity licensing reports run automatically.

The nbdeployutil utility supports incremental reporting. NetBackup triggers nbdeployutil to run based on a specified schedule, incrementally gather data, and generate capacity based licensing reports for the past 90 days. There are no scheduled reports in traditional licensing. Reports for traditional licensing must be run manually.

Note: If you upgrade from an older version of nbdeployutil with incremental reporting to NetBackup 8.0 or later version, the operating system-based scheduler or Cron job is removed. NetBackup triggers nbdeployutil to run at a specified schedule, incrementally gather data, and generate capacity based licensing reports for the past 90 days.

The nbdeployutil utility can be scheduled to run capacity licensing reports, but not traditional licensing reports. See "Scheduling capacity licensing reports" on page 26.

Traditional or capacity licensing reports run manually.
 See "Generating licensing reports manually" on page 32.

Scheduling capacity licensing reports

By default, NetBackup triggers nbdeployutil to run on a specified schedule to incrementally gather data, and to generate capacity licensing reports for the past 90 days.

Incremental reporting parameters

Incremental reporting uses the following four parameters:

- FREQUENCY_IN_DAYS: The frequency at which nbdeployutil is run.
- MASTER_SERVERS: A comma-separated list of the master servers.

- PARENTDIR: The gather and report folder location.
- PURGE_INTERVAL: The number of days that the folders retain the gathered data in the incremental directory.

To use the default values, See the section called "Use Case I: Use default values for parameters" on page 28.

To use the custom values, See the section called "Use Case II: Use custom values for parameters" on page 28.

The location where the data and reports are generated contains the following files:

- The generated report for the latest nbdeployutil result.
- Folders containing incrementally gathered data.
- The archive folder that contains the older generated reports.
- nbdeployutil log files.

The following directories contain the most current capacity licensing report:

On Windows: *Install_Dir*\NetBackup\var\global\incremental

On UNIX: /usr/openv/var/global/incremental

The older reports are placed in the archive folder. Veritas recommends that you retain at least 90 days of reporting data. Data can be kept longer than 90 days, depending on the requirements of your environment. Older reports can help to show how the capacity usage has changed over time. Delete the reports or the folder when they are no longer required.

Each time <code>nbdeployutil</code> is triggered, the information is gathered for the following duration: from the last successful run to the latest run of <code>nbdeployutil</code>. For the first run, the duration of the report is as per the frequency that is specified in the configuration file (default value is 7 days). The report duration is always for the last 90 days based on the availability of the gathered data. Any data older than 90 days is not considered in the report.

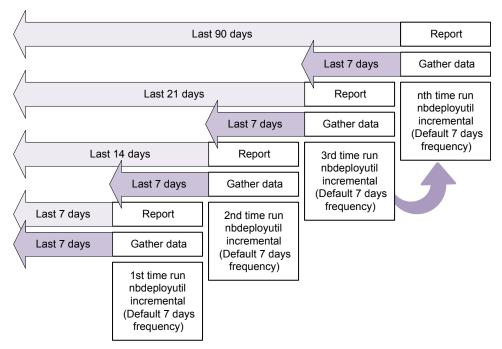

Figure 1-1 Generating incremental capacity licensing reports

Use Case I: Use default values for parameters

The nbdeployutilconfig.txt file is not required when using the default parameters. nbdeployutil uses the following default values:

- FREQUENCY_IN_DAYS=7
- MASTER_SERVERS=local_server
- PARENTDIR=folder_name
 - For Windows: Install Dir\NetBackup\var\global\incremental
 - For UNIX: /usr/openv/var/global/incremental
- PURGE_INTERVAL=180 (number of days).

Use Case II: Use custom values for parameters

Edit the nbdeployutilconfig.txt file.

To use custom values in the nbdeployutilconfig.txt file

1 Copy the nbdeployutilconfig.txt file to the following location:

For Windows: Install_Dir\NetBackup\var\global

For UNIX: /usr/openv/var/global

2 Open and edit nbdeployutilconfig.txt to change the parameters and then save the file.

FREQUENCY_IN_DAYS=number_of_days
 Based on the frequency that is indicated in this parameter, nbdeployutil gathers the data and generates the report.

Minimum value: 1 day.

By default, the frequency value is 7 days to capture optimum capacity usage data.

- If no value is indicated, nbdeployutil uses the default value.
- If the frequency indicated is 0, incremental reporting is disabled and no licensing information is captured.
- If the parameter is deleted, nbdeployutil uses the default value.
- MASTER_SERVERS=server_names

nbdeployutil gathers the information for each master server that is listed and generates the report.

- If there is no value in this parameter, nbdeployutil uses the default value.
- If you delete the parameter, nbdeployutil uses the default value.

Examples of server names:

- MASTER_SERVERS=newserver,oldserver
- MASTER_SERVERS=newserver,oldserver.domain.com
- MASTER_SERVERS=myserver1.somedomain.com,newserver.domain.com
- PARENTDIR=folder_name_with_path

To change the gather and report location, edit this parameter.

- If there is no value in this parameter, nbdeployutil uses the default value.
- If the parameter is deleted, nbdeployutil uses the default value.
- PURGE_INTERVAL=number_of_days

Any gathered data that does not fit into the purge_interval value is deleted automatically.

- If no value is indicated, nbdeployutil uses the default value.
- If the parameter is deleted, nbdeployutil uses the default value.
- If fewer than 90 days is indicated, nbdeployutil uses 90 days as the value. Data that is older than 180 days is purged.
 Data to be purged = current date purge_interval.
 Minimum value = 90 days.

Troubleshooting failures for nbdeployutil and incremental reporting

- If nbdeployutil fails to gather data and generate the report for your environment, refer to the logs to understand when the task failed and the reason for the failure.
- Errors related to bpimagelist after running nbdeployutil.
 If the manual run of nbdeployutil fails and a bpimagelist error with status 37 is displayed, ensure to add master servers as additional servers.
 For more information, See the section called "Gathering information for multiple master servers" on page 35.
- For Oracle Real Application Clusters (RAC), protected data size might get reported more than once because the size is reported for the node where data backup happens.

If the backup operation is initiated from different nodes in the Oracle Real Application Clusters (RAC), the capacity licensing report displays a separate row for every node.

 After running nbdeployutil, the following error is displayed because of internal web service communication failures: Report for master server <SERVER-NAME> is generated using the backup

image header method instead of accurate licensing method because of web service interruptions during the gather phase.

 For MS SQL multistriped data backups, the Itemization tab in the capacity licensing report displays one backup ID from the multiple backup IDs for one selection in the backup policy. In the reports for NetBackup 8.0 or earlier, multiple was displayed instead of back ID.

Other points to consider when using nbdeployutil and incremental reporting

To change the directory of the gathered data and licensing report

- 1 If you have older gathered data and licensing reports, copy the complete directory to the new location.
- 2 Edit nbdeployutilconfig.txt and change the location of the gathered data and licensing report in the PARENTDIR=folder name field.

To use the previously successful gathered data for generating a capacity licensing report

1 Copy the gather folder that was generated after previous run of nbdeployutil to the following location:

On Windows: Install_Dir\NetBackup\var\global\incremental

On UNIX: /usr/openv/var/global/incremental

2 Create the gather_end.json file inside the copied folder and add the following text:

{"success":0}

The next incremental run considers the data inside the copied folder to generate a capacity licensing report.

Note: Delete any other gather folders inside the copied folder to avoid gaps for the period in which data is gathered. The missing data is automatically generated during the next incremental run.

To create a custom interval report using existing gathered data

 To create a report for a time interval that is different than the default interval of 90 days, run the following command:

On Windows:

```
nbdeployutil.exe --capacity --incremental --report --inc-settings
"<Install_Dir>\netbackup\var\global\nbdeployutilconfig.txt"
--hoursago <custom-time-interval>
```

On UNIX:

```
nbdeployutil.exe --capacity --incremental --report --inc-settings
"/usr/openv/var/global/nbdeployutilconfig.txt" --hoursago
<custom-time-interval>
```

The number of hours specified in --hoursago must be fewer than the purge-interval that is specified in the nbdeployutilconfig.txt file.

Note: nbdeployutil uses existing gathered data to generate the custom interval report. You are not required to use the --gather option.

Generating licensing reports manually

Run the nbdeployutil utility to gather data for a local master server, a remote master server, or a subset of clients. nbdeployutil can be run manually to generate a report for either the capacity or the traditional reporting model.

The utility generates the report in multiple steps. Data is gathered in the first step, and then analyzed and presented. The utility is located in the following directory:

On Windows: Install dir\NetBackup\bin\admincmd\

On UNIX: /usr/openv/netbackup/bin/admincmd/

Task Number	Description
Task 1	The nbdeployutil utility uses the following options to gather data from one or more master servers.
	<pre>nbdeployutilgather [output=DIRECTORY] [capacity traditional] [hoursago=N] [start="mm/dd/yyyy HH:MM:SS" [end="mm/dd/yyyy HH:MM:SS"]] [clientlist=FILENAME clients=HOSTNAME[,] [master=HOSTNAME[,]] [log=FILENAME] [runtimestats] [nolog] [bpimagelist=OPTIONS [use-bpflist]</pre>
	The nbdeployutil utility gathers data remotely for multiple master servers from a central location, provided the master servers have granted the initiating server access. The utility supports collecting data remotely from back-level master servers. Load the engineering binary that is associated with this utility onto all master servers for which you want to gather information.
Task 2	The nbdeployutil utility uses the following options to analyze the gathered data and prepare the report:
	<pre>nbdeployutilreport <capacity traditional=""> <directory> [dirlist=FILENAME parentdir=DIRECTORY] [capacity] [debug-inputs] [log=FILENAME] [clientlist=FILENAME clients=HOSTNAME[,] [day-boundary=TIME] [runtimestats] [nolog] [overlap-details]</directory></capacity></pre>
	For a traditional report, run: nbdeployutilreporttraditiona: For a capacity report, run: nbdeployutilreportcapacity

 Table 1-4
 nbdeployutil options to gather, analyze, and prepare reports

On the master servers that have NetBackup 8.0 or later, when you manually run <code>nbdeployutil</code> for the gather operation in capacity licensing, you must enter the following credential information for authentication of the NetBackup web management service:

Option	Description
Domain Type	Enter a domain type value from NIS, NISPLUS, WINDOWS, vx, unixpwd, Idap. This value is case-sensitive.
Domain Name	Name of the domain that the master server host belongs to. If the master server does not belong to any domain, enter the name of the master server.
User name	Name of the user that has administrator privileges.
Password	Password of the same user that has administrator privileges. When you enter the password, characters are intentionally not displayed in the command line.

 Table 1-5
 Required credential information

In a multi-master server scenario, you must enter the credentials for all the master servers that are mentioned with the gather command.

Note: You must update any automation that you might have done of the nbdeployutil gather process for NetBackup master server 8.0 or later. This update is required because of the changes in nbdeployutil to accept user credentials.

The performance of the nbdeployutil utility is dependent on the system running it as well as the size of the NetBackup catalog. The --gather option only executes as quickly as the bpimagelist command can run for 90 days' worth of images. The speed of report generation is dependent on the number of images and fragments. The operating system running the command also affects the utility's performance.

Depending on the environment, the nbdeployutil utility can take from several seconds to several minutes to run the --gather or the --report options.

Veritas posts the most recent information about the nbdeployutil utility on the following website:

http://www.veritas.com/docs/TECH145972

Gathering information for the local master server

In this example, the nbdeployutil utility is used to gather information for the local master server. Use the --capacity or the --traditional option, depending on the type of report you want to generate

```
C:\Program Files\Veritas\NetBackup\bin\admincmd>nbdeployutil --gather
NetBackup Deployment Utility, version 8.1
Gathering license deployment information...
Discovered master server master.example.com
```

```
Master Server:master.example.com
  Domain Type (NIS, NISPLUS, WINDOWS, vx, unixpwd, ldap):WINDOWS
  Domain Name:example.com
 User Name:Administrator
  Password:
  Output for master.example.com at:
  C:\Program Files\Veritas\NetBackup\var\global\reports\
   20160525 151315 master.example.com
Gather DONE
Execution time: 9 secs
To create a report for this master server, run one of the following:
  capacity : nbdeployutil.exe --report --capacity
  "C:\Program Files\Veritas\NetBackup\var\global\reports\
   20160525 151315 master.example.com"
  traditional: nbdeployutil.exe --report --traditional
  "C:\Program Files\Veritas\NetBackup\var\global\reports\
   20160525 151315 master.example.com"
```

The utility generates a log file named nbdeployutil-gather-timestamp.log during the gathering operation. By default, the log file is created in the directory where the gathered data resides.

Gathering information for a remote master server

nbdeployutil --gather --master=sidon.example.com

Gathering information for a subset of clients that the local master server protects

nbdeployutil --gather --client=dynamo,lettuce,marble2

or

nbdeployutil --gather --clientlist=filename.txt

Note: When the --clients or the --clientlist option is used, some media servers may show in the report as not connectable, even though the utility can connect to them. This message does not affect the summary information.

Gathering information for multiple master servers

Before you run nbdeployutil in a multi-master servers environment, complete the following steps as a one-time activity:

1. Create a trust relationship between the master servers.

For more information, refer to the Adding a trusted master server topic, from the *Veritas NetBackup*[™] Administrator's Guide, Volume I.

 On every remote master server in the multi-master server environment, add an entry of the master server where you plan to run nbdeployutil. From the NetBackup Administration Console, navigate to Host properties > select
 Master Servers > right-click the remote master server > click Properties > select Server > add the master server entry in the Additional Servers tab.

Creating and viewing the licensing report

After using nbdeployutil to gather report data, use the --report --traditional or --capacity option to generate a licensing report in the form of a Microsoft Excel spreadsheet.

Use the utility to generate a report for any of the following:

- A single master server.
- Several master servers.
- A specific subset of clients. For example, a report that contains capacity usage for business unit billing.

Creating a report using data that is collected for the local master server

The --gather --capacity command is run for master server cayce.rm.com:

```
C:\Program Files\Veritas\NetBackup\bin\admincmd>nbdeployutil.exe
--gather --capacity
NetBackup Deployment Utility, version 8.0Beta1
Gathering license deployment information...
Discovered master server cayce.rm.com
Output for master server at:
C:\Program Files\Veritas\netbackup\var\global\reports\20160527_140620_cayce
Gather DONE
Execution time: 2 secs
```

To create a capacity report based on the data gathered, the utility tells you what command you need to run:

```
To create a report for this master server, run the following:
    nbdeployutil.exe --report --capacity
"C:\Program Files\Veritas\netbackup\var\global\reports\20160527_140620_cayce.
C:\Program Files\Veritas\NetBackup\bin\admincmd>nbdeployutil.exe
```

```
--report --capacity
"C:\Program Files\Veritas\netbackup\var\global\report\20160527_140620_cayce.r
NetBackup Deployment Utility, version 8.0Beta1
Analyzing license deployment ...
Following directories were given, but do not exist:
    C:\Program Files\Veritas\netbackup\var\global\report\20160527_140620_
cayce.rm.com
```

The utility generates a log file named nbdeployutil-report-timestamp.log during the analysis and the report generating operation. By default, the log file is created in the directory where the gathered data resides.

Creating a roll-up report for several master servers

This example assumes that you have gathered the respective master server's data in directories masterldir, masterldir, masterldir. These directories all reside within a parent directory named EMEA-domains. The output (report and log file) is saved to the EMEA-domains directory.

nbdeployutil --report --parentdir=EMEA-domains

This variation creates a report for a smaller set of master servers and specifies a different directory for the output.

```
# mkdir UK-masters
# nbdeployutil --report EMEA-domains/master1dir EMEA-domains/master2dir
--output=UK-masters
```

Creating a report for a set of clients or for a business unit

The utility can be used to examine a specific set of clients in detail.

Example: Gather data for a subset of clients for a time frame different than the default.

```
nbdeployutil.exe --gather --output BusinessUnitFinance --start "11/01/10
06:00:00" --end "11/02/10 01:00:00" --clients marybl2g1,marybl7g1
--verbose
```

To create a report for these clients, run the following:

nbdeployutil.exe --report "BusinessUnitFinance\20101102 155246 marybl2g1"

Report tab descriptions

The nbdeployutil utility examines the image headers in the NetBackup catalog to determine one of the following:

- For traditional licensing, nbdeployutil determines the servers and clients in the NetBackup environment.
- For capacity licensing, nbdeployutil determines the amount of data NetBackup
 protects. The way that the client policies and schedules are configured can affect
 the results.

The licensing report is a Microsoft Excel spreadsheet. The tabs that appear in the spreadsheet depend on whether the report is a traditional or a capacity licensing report.

Tab	Description	Report type
Summary	 The contents of this tab differs for a traditional or a capacity report. Traditional report: Shows the final details about master servers, media servers, and clients. This tab lists the source data for generating the report. The number of media servers and the number of clients is provided, as well as capacity information. Capacity report: Shows the final figures, an overview of the basis for the report (data source), and a breakdown of the source of the capacity. The capacity breakdown includes a reporting by policy type and largest clients. 	Traditional and capacity
Itemization	Displays a table similar to the line itemization table you may see in a credit card bill. Each line is a charge that contributes to the final total. Each line lists the capacity that is calculated for a client or policy combination.	Capacity
Unused clients	Displays the names of clients that are registered with the master server but are not backed up.	Capacity
Hosts	A listing of host names, along with associated computer information. The associated information includes information such as: platform, computer type, database software installed, SAN media server, and NDMP.	Traditional
NDMP	A list of computers that are NDMP servers and the corresponding tier number of the client. When you reconcile the report, you need to address the clients that are found on this tab.	Traditional
Virtual Servers	A list of the virtual servers or the virtual hosts that were detected in the environment.	Traditional

Table 1-6Report tab descriptions

Tab	Description	Report type
Drives	Details the type of drives and the host or the library where the drive resides. Lists the host names that are associated with each drive as well as information about virtual tape libraries, shared drives, and vaulted drives.	Traditional
Interpreting the Results	Explains how to examine the report and how to reconcile the information in the report with your actual environment.	Traditional and capacity

Table 1-6Report tab descriptions (continued)

After creating a traditional licensing report

After using nbdeployutil to gather report data, use the --report --traditional option to generate a traditional licensing report in the form of a Microsoft Excel spreadsheet.

This topic reviews the different tabs that appear in a traditional licensing report and describes the process of reconciling the report with the actual NetBackup environment.

Use the following steps to examine the report results:

Step	Description	Reference
1	Examine the Summary tab and confirm that the correct information is displayed.	See "Verify the Summary tab" on page 40.
2	Review the Hosts tab and resolve any missing information.	See "Complete the Hosts tab" on page 40.
3	Review the NDMP tab and resolve any missing information.	See "Resolve the NDMP tab" on page 41.
4	Review the Virtual Servers tab and resolve any missing information.	See "Update the Virtual Servers tab" on page 42.
5	Review the Drives tab and resolve any missing information.	See "Confirm the Drives tab" on page 42.

Table 1-7 Examining the traditional licensing report

Verify the Summary tab

The top of the report's **Summary** tab details the basis for the report's information. Review the **Period Analyzed** for the source of the information for the report. The **Period Analyzed** section includes:

- Start date for the gather for each master server.
- End date for the gather for each master server.
- The total number of days gathered for each master server.
- The input directory for each master server that is associated with the report.

The start and the end dates are not necessarily the dates that are specified for the --gather option. These are the dates within the time period that you specified where images exist. If images do not exist for a specified start or end day, the day is not listed. The nearest date with backup images is included and listed.

The **Input Directory** column displays the path to the gathered data. Within the **Input Directory** is the nbdeployutil-gather-*timestamp*.log file. If non-default inputs were used in the collection of catalog data, the log file displays this information.

Under the **Options** section, confirm that the list of master servers is correct. If there are missing or extra master servers, rerun the report.

When the review of the entire report is complete, all the values in the **Unknown** row under **Tiering** should be zero. As you reconcile the other tabs in the report, these values automatically update to zero.

Complete the Hosts tab

The **Hosts** tab provides a listing of all media servers and client servers that are included in the report. The tab includes master servers if they are either a media server or a client server. Review five areas to complete the review of this tab.

To complete the Hosts tab

Scan the **Connectable** column to see if the utility was unable to connect to any hosts for its calculations. Be aware the utility cannot connect to NDMP filers. If there is a large number of non-NDMP filer hosts the utility could not connect to, consider rerunning the utility with the --retry option. Use the following command to retry the connections:

nbdeployutil --retry path_to_the_gathered_data

When the command finishes, use the following command to recreate the report.

nbdeployutil --report all_previously_specified_options
all previously specified gather directories

- 2 Check the Tier column for any hosts that are listed as UNKNOWN. Replace these with the appropriate tier number between one and four. Work with your Veritas Sales Engineer to determine the correct tier information. The Platform and Processors values help determine the host's tier. These columns do not calculate the tier, but by knowing this information you can determine the appropriate value to enter in the Tier column.
- 3 Review the **MSEO Key Server** column and verify that all the listed information is correct. Yes indicates that the host is an MSEO key server. No indicates that the host is not an MSEO key server. The N/A value indicates that the host is not a media server.
- 4 Check the **Enterprise Client** column and verify that the information is correct. Yes indicates that the host is an enterprise client and was backed up. No indicates that the host is not an enterprise client. The N/A value indicates that no backups were performed on the host during the report period.
- 5 Review the SAN Media Server column and correct any hosts where the value is UNKNOWN. Confirm that all other values are correct. A value of N/A for a host indicates that the host is either a client server or a master server.

Be aware that the only column which contributes to the final information on the **Summary** tab is the **Tier** column. Values of **UNKNOWN** in other columns other than **Tier** indicate unknown information. All data aside from the **Tier** column is for informational purposes only

Resolve the NDMP tab

The **NDMP** tab lists the hosts that the utility has determined to be NDMP servers. If there are servers listed which are not NDMP servers, delete these servers from the list. Add any missing NDMP servers to the list. For all servers, review the **Tier** column and confirm that the information is correct. Any **Tier** values of **UNKNOWN** should be replaced with the correct tier number between one and four. Work with your Veritas Sales Engineer and the NetBackup Pricing and Licensing Guide to determine the correct tier information.

Update the Virtual Servers tab

Complete the Virtual Servers tab. Replace any UNKNOWN values under the Used column with Yes or No. Yes indicates that the host uses the NetBackup ESX-specific feature. No indicates that it does not use the feature. Add missing virtual servers to the list and indicate Yes in the Used column.

Confirm the Drives tab

On the **Drives** tab, review the information in the **VL** column. Verify that all virtual tape libraries are correctly listed as **Yes**. If a virtual tape library has No for a value in the **VTL** column, change the value to **Yes**. Change the value for **VTL** to **No** for any drives that are incorrectly marked as a virtual tape library.

Final steps

Once you reconcile the report, correct the errors and enter the missing information. Compare the results to the install base report. The install base report is provided to you by Veritas or your reseller. Confirm that everything in the report matches with the content in the install base report. If there are discrepancies, Consult with your Veritas sales representative to correct any discrepancies.

After creating a capacity licensing report

After using nbdeployutil to gather report data, use the --report --capacity option to generate a capacity licensing report in the form of a Microsoft Excel spreadsheet.

This topic reviews the different tabs that appear in a capacity licensing report and provides an overview on the process of reconciling the report with the actual NetBackup environment.

Use the following steps to examine the report results:

Step	Description	Reference
1	Verify the completeness of the report inputs.	See "Verify the completeness of the inputs" on page 43.

Table 1-8 Exa

Examining the capacity licensing report

Step	Description	Reference
2	Eliminate redundant data due to client aliases and multiple IP addresses.	See "Eliminate redundant data due to client aliases and multiple IP addresses" on page 44.
3	Examine the Itemization tab for flagged conditions in the Accuracy column.	See "Examine the Itemization tab for flagged conditions in the Accuracy column" on page 45.
4	Verify correct grouping and summation of multistreamed backup images.	See "Verify correct grouping and summation of multistreamed backup images" on page 47.
5	Examine the CloudCatalyst (KB) column that displays the volume of data processed using NetBackup CloudCatalyst	See "Examine the CloudCatalyst (KB) column that displays the volume of data processed using NetBackup CloudCatalyst" on page 47.
6	Examine overlap detection by nbdeployutil	See "Examine overlap detection by nbdeployutil" on page 47.

 Table 1-8
 Examining the capacity licensing report (continued)

Verify the completeness of the inputs

The top of the **Summary** tab shows the basis for the report information. Examine the section marked **Analyzed** to verify the completeness of the gathered data upon which the report is based.

The Analyzed section displays the following information:

- The master server(s) included in the report.
- The date range for catalog data.
- The number of clients and policies that are included in the catalog output.

If the client and the policy counts are low, the report may be based on the data that was gathered with narrower, non-default inputs. The analyzer gathers 90 days' worth of catalog data for all clients by default.

The **Input Directory** column displays the path to the gathered data. Within the **Input Directory** is the nbdeployutil-gather-timestamp.log file. If non-default inputs were used in the collection of catalog data, the log file displays this information.

1	Capacity Licensing Report

14	Total				24	30	0			

For the agents that support accurate licensing, on the **Summary** pane, under **Flagged Capacity Figures (TB)**, the **Overlap** column appears. The **Overlap** column displays the summation of the charged sizes for all overlapping policies. These are policies for which the **Overlap** keyword appears in the **Accuracy** column, per master server. The overlap is calculated only within the same policy type. For example, an **MS-Windows** policy backs up an Exchange or SQL database file that is already backed up using the **MS-Exchange-Server** or **MS-SQL-Server** policy type. Accurate licensing does not consider this policy as an overlap.

If data is reported using catalog image headers, the information is displayed in the **Possible Overlap** column.

26		Flagged Capacity Figures (TB)										
27	Master Server	Confirmed (TB)	Overlap	Database Estimation	Possible Overlap	Multistream Estimation						
28	master	0.00	48.00	64.00	16.00	64.00						
29	newmaster	0.00	70.00	70.00	0.00	70.00						
30	oldmaster	0.00	0.00	25.45	25.45	25.45						
31	upgradedmaster	0.00	90.50	105.70	15.20	105.70						
32	Total	0.00	208.50	265.15	56.65	265.15						

Eliminate redundant data due to client aliases and multiple IP addresses

The analyzer performs calculations based on the client name as stored in the catalog. Clients that are backed up by multiple aliases or multiple IP addresses are not collapsed into a single entry. For ease of accountability, the **Itemization** tab lists all client aliases and IP addresses used for backup separately. In some jurisdictions, the collection of the system IP address may be subject to regulation as personal data.

Determine where multiple client or policy lines refer to the same data set backed up through different interfaces. Make adjustments to the **Charged Size** value for all but one of the client or policy lines. We recommend retaining the value that is most recent. Annotate the duplicate client itemizations with a comment within the adjacent **Reason** cell. Indicate that the client's value is already counted under a different host name and reference the host name.

Examine the Itemization tab for flagged conditions in the Accuracy column

The report's **Itemization** tab shows the calculated capacity for each client or policy combination. The report flags any conditions that have the potential to over count or to under count capacity. These conditions are identified in the **Accuracy** and **Accuracy Comment** columns.

1	Master Serve	Client Name	Policy Name	· Po	alicy Type	٠	Backup Image	¥	Backup Date *	Accuracy	- 4	Accuracy Comment	
26	master1	RSVB3AVSPAP00	APP14_SMS_AV	M	S-Windows-NT		RSV83AV5PAP00_1285926056	F.	10/01/2010	OK

OK - Precise data is reported

Data that is displayed in the **Charged Size** column is protected data for a policy. A user can verify that the data is precise by referring to the policy type. See "Eliminate redundant counting of clients" on page 50.

Overlap - Same policy type for accurate licensing

Overlap is identified within the same policy type when the accurate licensing method is used. This means that if the same data is backed up more than once by different policies of the same type (within the same client or across clients in the same master server), the overlap is identified. You can see overlap values in the **Accuracy** column of the **Summary** tab for the agents that support accurate licensing.

The **MS-Windows**, **VMware** and **Standard** policy types support the following overlap scenarios:

- If identical policies of the same type exist, the policy with the largest backup size is charged to the user. The Charged Size column displays zero for one of the identical policies.
- If a policy is a subset of another policy (consumed policy), the Charged Size column displays zero for the consumed policy. The user is charged for the superset policy.
- If multiple polices have intersecting backup selections, the Charged Size column displays the reported size as it is. The user needs to verify and update the charged size column.

See "Verify the completeness of the inputs" on page 43.

Possible overlap - Client appears in multiple policies

A client in multiple backup policies has the potential to have the same data backed up more than once. Compare the policy types and names to determine if the case warrants a detailed examination of the respective policies' backup selections.

Database estimation - database size estimated using UBAK summation

The size of databases that a NetBackup database agent protects cannot be determined with certainty. Third party components external to NetBackup (for example, RMAN) govern the composition of database backups. The third-party component determines the number of backup streams and the contents of each stream. These backups are recorded as user-initiated backup images, or UBAKs. NetBackup does not initiate backup streams, nor does it know each stream's relationship to the underlying database. Therefore the information in the catalog does not provide a single, clear, undisputable figure for the total size.

In these cases, the analyzer calculates an estimation upon which to base follow-on examinations. The analyzer uses the image header information to determine the total terabytes of data that were backed up each day within the date range examined. A day is defined as the 24-hour period from midnight to midnight. The analyzer sums all full and user-initiated backups that started within that period. The day with the largest total volume of protected data during the range that is examined is assumed to be the day when a full backup of the database was performed. This figure that is returned is an estimate of the approximate size of active data under protection for the client and policy.

Undiscoverable - No full backup found within range analyzed

The catalog has only incremental backups for the range analyzed. That error may indicate that a full backup falls outside the report's range or that a full backup does not exist.

Compressed Image

The client's data was sent to NetBackup in compressed form. The actual size cannot be determined with certainty. For all compressed backup images, the analyzer multiplies the final backup image size by a fixed value (the compression ratio). The value of the compression ratio is listed on the **Summary** tab.

Size unavailable – Only snapshot is present

The catalog has only snapshots for the range analyzed. The analyzer requires a backup image of the snapshot to have an accurate figure for the client's protected capacity.

Possible multistream backup detected

The size of the clients that are protected by multistream backups is the total of all backup images that are created by all streams.

Verify correct grouping and summation of multistreamed backup images

When a client is backed up by multiple streams, the client's size is equal to the total of all backup images that were created by all streams. Job throttles on the policy, the client, and the storage unit hinder the utility's ability to group the streams with certainty. For example, instead of starting within minutes of one another a subset of the backup streams may start in a different day than the rest of the backup streams. Because the utility sums only the backup images from streams that originate within the same 24 hour period (midnight to midnight), these streams are counted in separate days. Manually initiating a second full backup within the same day also skews the results. Streams from both backups are counted together as a group.

Examine the CloudCatalyst (KB) column that displays the volume of data processed using NetBackup CloudCatalyst

From NetBackup 8.1, the **CloudCatalyst (KB)** column in the itemization sheet of the licensing report displays the volume of the Front-End Terabyte data that is processed using NetBackup CloudCatalyst. The NetBackup CloudCatalyst feature deduplicates and then stores the data in a cloud storage server.

The **CloudCatalyst (KB)** column is available for both capacity and traditional licensing reports. In a capacity licensing report, the **PureDisk (KB)** and **Accelerator (KB)** columns display the volume of data that comes from MSDP and Accelerator respectively and then is processed using NetBackup CloudCatalyst.

In the following figure, for the *pol_cloudcatalyst* policy, the **PureDisk (KB)** column displays that 275936 KB data is processed using NetBackup CloudCatalyst. Similarly, for the *pol_cloudcatalyst_accelerator* policy, the **Accelerator (KB)** column displays that 275936 KB data is processed using NetBackup CloudCatalyst.

Figure 1-2 CloudCatalyst (KB) column

Policy Name	7 Charged Size (8 -	 N8 Deduplication (X - 	BasicDisk (KB -	AdvancedDisk (KE -	PureDisk (K8 -	Accelerator (KE -	OpenStorage (K) -	CloudCatalyst (KB) -
pol_cloudcatalyst	275936	275936	0	0	275936	0	0	275836
pol_cloudcatalyst_accelerator	275936	275936	0	0	0	275936	0	275936
pol_msdp	275936	275936	0	0	64	0	0	0
pol_msdp_accelerator	275936	275936	0	0		64	0	0

Examine overlap detection by nbdeployutil

On NetBackup clients 8.1 or later, when you run nbdeployutil, either manually or using the incremental reporting feature, overlapping backup selection data is detected and automatically adjusted for the overlapping policies in the **Charged Size** column of the report. nbdeployutil detects if the same data is backed up by multiple policies of the same policy type and deducts the charged size for overlapping

backup selections. This feature ensures that you are charged optimally for capacity licensing and are not charged for duplicate backed up data.

To enable overlap detection, run the nbdeployutil report with the following option:

Table 1-9Option for overlap details

Command line option	Description
overlap-details	Use this option while generating the capacity licensing report to display duplicate backup selections in the Duplicate Selections column of the report.
	Note: Use this option only for ASCII or English-only characters in the backup selection data.
	The following disclaimer is displayed when you run this option:
	The overlap-details flag creates the Duplicate Selection column with data, which can be potentially sensitive.

For example, if you have the following backup policies for policy type Microsoft SQL Server:

Table 1-10Policies

Policy1	Policy2				
Backup Selection:	Backup Selection:				
"MSSQLSERVER"/"DB1"/ [Size 1.4GB]"MSSQLSERVER"/"DB2"/ [Size 1.4GB]	 "MSSQLSERVER"/"DB2"/ [Size 1.4GB] "MSSQLSERVER"/"DB3"/ [Size 1.4GB] 				

Here MSSQLSERVER is the name of instance and DB1, DB2, DB3 are the databases. The DB file DB2 is common in both policies Policy1 and Policy2. nbdeployutil detects the overlap and displays in the report.

Policy Name	Accuracy	Accuracy Comment	Overlap Size (GB)	Duplicate Selection	Total (Readable) Size (GB)	Charged Size (GB)
Policy1	ОК		0		2.8	2.8

Policy Name	Accuracy	Accuracy Comment	Overlap Size (GB)	Duplicate Selection	Total (Readable) Size (GB)	Charged Size (GB)
Policy2	ОК	Overlap detected for the policy and deducted from the Charged Size	1.4	'MSSQLSERVER'/ <i>«PLACE_HOLDER»/</i> "DB2"/	2.8	1.4

 Table 1-11
 Sample report columns (continued)

In case of Availability Group (AG) the <PLACE_HOLDER> contains the AG name.

Reconciling the capacity licensing report results

After reviewing the resulting spreadsheet you can either:

- Accept the generated information without changes as the basis for license charges.
- Make changes and note the reason for the change.

As you make changes to the spreadsheet assess when any additional changes are no longer meaningful. Since licensing charges are assessed on a per terabyte basis, it may not be beneficial to dispute charges for a few gigabytes of information. You may want to sort the clients by their backup size and focus on the largest backups first. Sorting by backup size provides two benefits. First, your efforts are initially focused on the largest clients. Second, if there are clients backing up only a few kilobytes, these backups may not capture the correct information. You may have important data which is unprotected.

Locate full backups for clients

On the **Itemization** tab, sort the list by the **Accuracy** column. For all rows that indicate Undiscoverable, manually query the NetBackup catalog to determine if a full backup can be found. A full backup may exist in a time period that precedes the period the analyzer examined. Run the utility again with specific options to restrict the collection and reporting to the specific client and a specific date range within which the full backup(s) fall. Alternatively, manually examine the client system to determine the size of data that would be backed up with the backup policy's selections and settings.

Review compressed image information

On the **Itemization** tab, sort the list by **Accuracy** column. For any compressed images, review the **Charged Size** column and confirm that the correct information is displayed. If the information is inaccurate, change the **Charged Size** column, and add a note to the **Enter a Reason here when modifying the Charged Size** column explaining the change.

Eliminate redundant counting of clients

On the **Itemization** tab, sort the list by **Client Name** and search for the use of host name aliases. Look for instances where the itemization table lists the same client multiple times under the same policy but with a different host name alias. If that occurs, zero out the **Charged Size** column for the lines with an earlier backup date. Add a note to the **Enter a Reason here when modifying the Charged Size** column explaining why the **Charged Size** value is zero.

For some Oracle RAC backups, the presence of itemizations under different aliases can reflect the backup of different data sets. If you zero out the **Charged Size** the protected data is under counted.

If a client is found in more than one policy, confirm that those policies do not have overlapping backup selections. If the backup selections overlap, find the redundant backup policies in the **Itemization** tab. Make adjustments to the **Charged Size** value. Decrement the size by the value of the redundant backup selection and add a comment within the adjacent **Reason** cell.

Note: For the agents that support accurate licensing, multiple host name aliases do not exist.

Determine the effect of multistreamed backups

On the **Itemization** tab, sort the list by the **Accuracy** column. Find all backups that list **Possible multi-stream backup detected** and make a note of the policy name under the **Policy Name** column. Open the log file that was generated when the <code>nbdeployutil --report</code> command ran. By default, the log file is in the directory where the gathered report is located.

Note: If OpsCenter generated the report, the log file is found on the OpsCenter server. The email with the report results contains a link to the log file location. The log file name is in the format nbdeployutil-report-timestamp-log.

In the log file, find the policy name for the policy in question and look at the corresponding **MAX** value. The excerpt from a log file that is shown highlights the information discussed.

```
Analyzing backups for policy <policy_name>, client <client_name>
Analyzing schedule Full

MAX 2010-09-01 14.6 T (multiple backups )

21.7 G (client_name_1283295642) 09:00:42

1.0 T (client_name_1283295643) 09:00:43

793.1 G (client_name_1283295644) 09:00:45

1.2 T (client_name_1283295645) 09:00:48

1.5 T (client_name_1283295647) 09:00:49
```

Confirm that this information is correct for the policy. If the information is inaccurate, update the **Charged Size** column, and add a note to the **Enter a Reason here when modifying the Charged Size** column that explains the change.

Confirm the accuracy of any database backups

Reconcile database backups in the same way that you reconcile multistream backups. Find the policy name in the spreadsheet and locate the analyzed information in the nbdeployutil-report-timestamp.log file. Does the chosen day appear to correspond to a day upon which the complete database was backed up? If the information is inaccurate, change the **Charged Size** column, and add a note to the **Enter a Reason here when modifying the Charged Size** column explaining the change.

Locate full backups for snapshot images

Examine the backup policy attributes to determine if a backup image is ever created from the snapshot. If it is, rerun the analyzer with specific options to restrict the collection and reporting to the specific client with a longer date range to find a full backup of the snapshot. If a backup image is never created from the snapshot, manually examine the snapshot or the client system to determine the size of the data.

Note: The log file that is associated with this report shows snapshot information.

Chapter

Additional configuration

This chapter includes the following topics:

- About multiple NetBackup master servers
- About multiple media servers with one master server
- About direct I/O for backups on Windows
- About dynamic host name and IP addressing
- About busy file processing on UNIX clients
- About specifying the locale of the NetBackup installation
- About the Shared Storage Option
- About the vm.conf configuration file

About multiple NetBackup master servers

For a large site, use multiple NetBackup master servers to optimize the backup loads. Divide the clients between the servers as necessary.

Figure 2-1 shows a multiple-server configuration where the two sets of networks (A1/A2 and B1/B2) each have enough clients to justify separate servers.

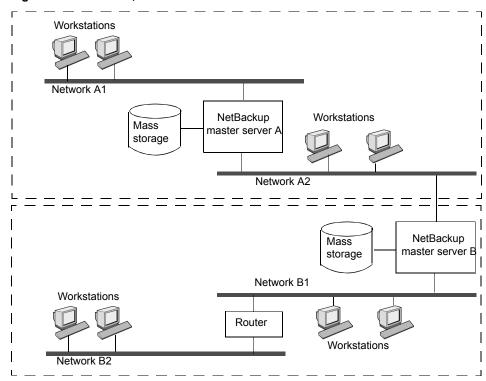

Figure 2-1 Multiple master server scenario

In this environment, the two NetBackup server configurations are completely independent. You can also create a configuration where one server is the master and the other is a media server.

About multiple media servers with one master server

A protection domain refers collectively to the NetBackup master server, its NetBackup media servers, and its NetBackup clients. In a group of NetBackup servers, a client can have backups directed to any device on any server in the group.

Set up a NetBackup protection domain as follows:

- One master server, which controls all backup scheduling.
- Multiple media servers, which write the backup images to disk or removable media. They can have peripheral devices to provide additional storage.

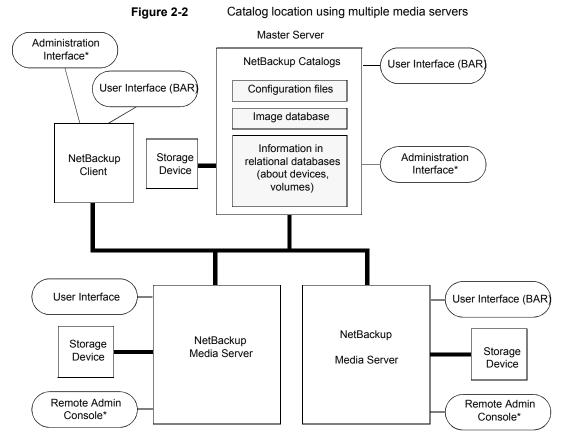

• Multiple protected NetBackup clients, which send their data to the media servers.

A common alternative strategy is to install extra peripherals on the clients that produce large amounts of data. The master server directs the data from the client to the client's peripherals, which reduces network traffic because the data does not traverse the network. This strategy also distributes the backup load between the master and the media servers.

Important factors to remember about master and media servers are as follows:

- There can be only one master server in a group.
- A NetBackup master server is a media server for itself but cannot be a media server for another master server.

Figure 2-2 shows where software is installed and where the NetBackup catalogs are located (by default).

* You can also use the Backup, Archive, and Restore user interface from a Windows client that has the Remote Administration Console installed.

About the software on each server

Install NetBackup server software on each NetBackup server that has a peripheral that you want to include in a storage unit. The NetBackup installation program has choices for master and media server installation.

About NetBackup catalogs

The master server is the default location for the NetBackup catalogs. The catalogs include the media and the volume database ($emm_data.db$). The volume database contains the media usage information and the volume information that are used during the backups.

About direct I/O for backups on Windows

By default, the buffer size for disk storage units is 256 KB. If the buffer size is set to a value greater than 256 KB, backups written to that storage unit automatically use direct I/O. An increased buffer size can improve backup speed.

To increase the buffer size, the following conditions must be met:

- A Windows media server must own the storage unit.
- The storage unit must be either a BasicDisk or an Array Disk storage unit.
- The backup to be stored cannot be multiplexed.
- The touch file that disables direct I/O must not be present.

(install path\VERITAS\NetBackup\bin\DISABLE DIRECT IO)

To increase the buffer size, create one of the following touch files on the media server that owns the storage unit:

For backups to disk

```
install_path\VERITAS\NetBackup\db\config\
SIZE_DATA_BUFFERS_DISK
```

For backups to disk or tape

```
install_path\VERITAS\NetBackup\db\config\
SIZE_DATA_BUFFERS
```

If both touch files are present, SIZE_DATA_BUFFERS_DISK overrides the value in SIZE_DATA_BUFFERS. At this time, Veritas recommends that you use SIZE_DATA_BUFFERS_DISK.

Table 2-1 shows the possible values to include in SIZE_DATA_BUFFERS_DISK or SIZE_DATA_BUFFERS.

Table 2-1 Absolute byte values for SIZE_DATA_BUFFERS_DISK, SIZE_DATA_BUFFERS

For a data buffer of this size (kilobytes)	Enter this touch file value
32	32768
64	65536
96	98304
128	131072

Table 2-1 Absolute byte values for SIZE_DATA_BUFFERS_DISK, SIZE_DATA_BUFFERS (continued)

For a data buffer of this size (kilobytes)	Enter this touch file value
160	163840
192	196608
224	229376
256	262144

Data buffer sizes continue in multiples of 32. Multiply the buffer size by 1024 for the touch file value.

A direct I/O backup triggers the following message: "Enabling direct I/O. Buffer size: <*buffer size*>."

Disabling direct I/O on Windows

To disable direct I/O

• Create the following touch file on the media server that owns the storage unit:

install path/VERITAS/NetBackup/bin/DISABLE DIRECT IO

About dynamic host name and IP addressing

Before making changes to a configuration, read this entire topic.

By default, a NetBackup server assumes that a NetBackup client name is the same as the network host name of the client computer. This assumption makes it difficult to back up any clients that have network host names that might change. For example, a computer that plugs into a LAN and obtains IP addresses from a DHCP server. Or, a remote machine that dials into a PPP server. Use dynamic host name and IP addressing to define NetBackup clients that do not have fixed IP addresses and host names.

If dynamic addressing is used, remember that the NetBackup servers still require fixed IP addresses and host names.

All clients that are configured to use dynamic addressing and host names must trust each other, similar to the NetBackup altnames feature.

The following process is required to support the configurations that use dynamic IP addressing for NetBackup.

Action	Process details/requirements		
Configure the network to use a dynamic IP addressing protocol like DHCP.	NetBackup requires that IP addresses of clients have a network host name.		
	(On Windows) Be sure to define network host names for the range of dynamic IP addresses in the hosts file and (or) DNS on the network.		
	(On UNIX) Be sure to define network host names for the range of dynamic IP addresses in the $\tt hosts$ file, NIS, and (or) DNS on the network.		
Determine the NetBackup client names for the computers that have dynamic IP addresses and network host names.	These NetBackup client names are used in other steps. Each NetBackup client must have a unique NetBackup client name. The NetBackup client name that is assigned to a client is permanent.		
Make changes on the master server, as described.	 Create NetBackup policies with client lists that include the new names. Create entries in the NetBackup client database for the new client names. Use the bpclient command to create the entries. 		
Make changes on each dynamic NetBackup Windows client, as described.	In the NetBackup Administration Console, in the left pane, click NetBackup Management. On the File menu, click Backup, Archive, and Restore. On the File menu, click NetBackup Client Properties. In the NetBackup Client Properties dialog box, select the General tab. Enter the correct NetBackup client name for the computer in the Client Name text box.		
On the master server, enable the Announce DHCP Interval option, as described.	In the NetBackup Administration Console , in the left pane, expand NetBackup Management > Host Properties > Clients . Double-click on the Windows client(s) in the right pane to open the Client Properties window. In the Client Properties window, in the left pane, expand Windows Client > Network . In the right pane, check the Announce DHCP Interval check box.		

Table 2-2Process to support the configurations that use dynamic IP
addressing for NetBackup

Action	Process details/requirements
Make changes on each dynamic NetBackup UNIX clients, as described.	 Modify the bp.conf file to include a CLIENT_NAME entry with the correct NetBackup client name for the computer. Configure the system to notify the master server of the computer's NetBackup client name and current network host name during startup. The bpdynamicclient command is used to notify the master server. Configure the system to notify periodically the master server of the computer's NetBackup client name and current network host name.

 Table 2-2
 Process to support the configurations that use dynamic IP addressing for NetBackup (continued)

About setting up dynamic IP addresses and host names

Configure the network to use a dynamic IP addressing protocol. A protocol like DHCP has a server and several clients. For example, when a DHCP client starts up, it requests an IP address from the DHCP server. The server then assigns an IP address to the client from a range of predefined addresses.

NetBackup requires that the IP addresses of NetBackup clients have corresponding network host names. Ensure that each IP address that can be assigned to NetBackup clients has a network host name. The host name should be defined in the host file, NIS, and DNS on the network.

For example, ten dynamic IP addresses and host names are available.

The dynamic IP addresses and host names might be as follows:

```
123.123.123.70 dynamic00

123.123.123.71 dynamic01

123.123.123.72 dynamic02

123.123.123.73 dynamic03

.

.

123.123.123.79 dynamic09
```

Assign a unique NetBackup client name to each NetBackup client that might use one of these dynamic IP addresses. The NetBackup client name that is assigned to a client is permanent and should not be changed. The client name that is assigned to NetBackup clients with dynamic IP addressing must not be the same as any network host names on the network. If the NetBackup client names are changed or are not unique, backup and restore results are unpredictable. For example, 20 computers share the IP addresses as previously defined.

To make these computers NetBackup clients, assign them the following NetBackup client names:

```
nbclient01
nbclient02
nbclient03
nbclient04
.
.
.
nbclient20
```

Configuring the NetBackup master server

Use the following procedure to configure the NetBackup master server.

To configure the NetBackup master server

- 1 On the master server, create the NetBackup backup policies. For client name lists, use the NetBackup client names (for example, *nbclient01*) rather than the dynamic network host names (for example, dynamic01).
- 2 Create the client database on the master server.

The client database consists of directories and files in the following directory:

On Windows:

install path\NetBackup\db\client

On UNIX:

/usr/openv/netbackup/db/client

3 Create, update, list, and delete client entries with the <code>bpclient</code> command. The <code>bpclient</code> command is in the following directory:

On Windows:

install path\NetBackup\bin\admincmd

On UNIX:

/usr/openv/netbackup/bin/admincmd

See "bpclient commands that control client entries" on page 62. In the example, enter the following commands to create the 20 clients: On Windows:

cd install path\NetBackup\bin\admincmd

On UNIX:

```
cd /usr/openv/netbackup/bin/admincmd
bpclient -add -client nbclient01 -dynamic_address 1
bpclient -add -client nbclient02 -dynamic_address 1
bpclient -add -client nbclient03 -dynamic_address 1
bpclient -add -client nbclient04 -dynamic_address 1
.
.
bpclient -add -client nbclient20 -dynamic address 1
```

4 To see what is currently in the client database, run bpclient as follows: On Windows:

install path/NetBackup/bin/admincmd/bpclient -L -All

On UNIX:

/usr/openv/netbackup/bin/admincmd/bpclient -L -All

The output is similar to the following:

```
Client Name: nbclient01
Current Host:
Hostname: *NULL*
IP Address: 0.0.0.0
Connect on non-reserved port: no
Dynamic Address: yes
```

```
Client Name: nbclient02
Current Host:
Hostname: *NULL*
IP Address: 0.0.0.0
Connect on non-reserved port: no
Dynamic Address: yes
.
.
.
Client Name: nbclient20
Current Host:
Hostname: *NULL*
IP Address: 0.0.0.0
Connect on non-reserved port: no
Dynamic Address: yes
```

The NetBackup client notifies the NetBackup server of its NetBackup client name and network host name. Then the Current Host, Hostname, and IP address fields display the values for that NetBackup client.

bpclient commands that control client entries

The <code>bpclient</code> command creates, updates, lists, and deletes client entries. The following table shows the <code>bpclient</code> commands that control client entries.

Command	
On Windows:	
bpclient.exe -add -client <i>client_name</i> -dynamic_address 1	
On UNIX:	
bpclient -add -client client_name -dynamic_address 1	
Where <i>client_name</i> is the NetBackup client name. The -dynamic_address 1 argument indicates that the client uses dynamic IP addressing. It's possible to create entries with -dynamic_address 0 for static IP addressing. However, to do so is unnecessary and adversely affects performance.	
On Windows:	
bpclient.exe -delete -client <i>client_name</i>	
On UNIX:	
bpclient -delete -client <i>client_name</i>	
On Windows:	
bpclient.exe -L -client <i>client_name</i>	
On UNIX:	
bpclient -L -client <i>client_name</i>	
On Windows:	
bpclient.exe -L -All	
On UNIX:	
bpclient -L -All	

 Table 2-3
 bpclient commands that control client entries

Configuring dynamic NetBackup clients

Configuring a dynamic Windows client

Use the following procedure to configure a dynamic Windows client.

To configure a dynamic Windows client

- 1 If it's not already installed, install NetBackup on the Windows client.
- 2 In the NetBackup Administration Console, in the left pane, click NetBackup Management. On the menu bar, expand File > Backup, Archive, and Restore.
- 3 On the menu bar of the Backup, Archive, and Restore dialog box, expand File > NetBackup Client Properties.
- 4 In the NetBackup Client Properties dialog box, select the General tab. Change the Client Name to specify the NetBackup client name for the Windows client. Click OK.
- 5 In the NetBackup Administration Console, set Announce DHCP Interval. This value specifies how many minutes the client waits before it announces that it will use a different IP address.

To set the Announce DHCP Interval, return to the NetBackup Administration Console. In the left pane, expand NetBackup Management > Host Properties > Clients. Double-click on the Windows client(s) in the right pane to open the Client Properties window. In the Client Properties window, in the left pane, expand Windows Client > Network. In the right pane, check the Announce DHCP Interval check box.

Additional information is available for **Announce DHCP Interval** in the NetBackup Administrator's Guide, Volume I.

The server is not notified if the default value of 0 is used. For a DHCP client, a good value to use is one-half of the lease period.

6 On the client, stop and restart the NetBackup Client service to have the changes take effect.

Configuring a dynamic UNIX NetBackup client

Use the following procedure to configure a dynamic UNIX NetBackup client.

To configure a dynamic UNIX NetBackup client

- 1 If not already installed, install the NetBackup client software.
- 2 Edit the /usr/openv/netbackup/bp.conf file. Use the CLIENT_NAME entry to specify the NetBackup client name for the computer, as follows:

CLIENT_NAME = nbclient00

3 Run the bpdynamicclient command once when the system first starts up. bpdynamicclient notifies the NetBackup server of the computer's NetBackup client name and current network host name. The bpdynamicclient command is in the directory:

```
/usr/openv/netbackup/bin
```

The format of the bpdynamicclient command is as follows:

bpdynamicclient -last successful hostname file name

When bpdynamicclient starts up, it checks for the existence of *file_name*. If *file_name* exists, bpdynamicclient determines if the host name that is written in the file is the same as the current network host name. If the host names match, bpdynamicclient exits and does not connect to the master server. If the host names do not match, bpdynamicclient connects to the master server and informs the server of its NetBackup client name and host name. If bpdynamicclient successfully informs the server, bpdynamicclient writes the current network host name into *file_name*. If bpdynamicclient cannot inform the server, bpdynamicclient deletes *file_name*.

Most UNIX systems provide a facility to define startup scripts.

For example, create the following script in the /etc/rc2.d directory on a Solaris system:

```
# cat > /etc/rc2.d/S99nbdynamicclient <<EOF
#! /bin/sh
rm /usr/openv/netbackup/last_successful_hostname
/usr/openv/netbackup/bin/bpdynamicclient
-last_successful_hostname \
/usr/openv/netbackup/last_successful_hostname
EOF
# chmod 544 /etc/rc2.d/S99nbdynamicclient</pre>
```

Ensure that the dynamic client startup script is called after the computer obtains its IP address.

4 You must also create a root crontab entry to call the bpdynamicclient command periodically.

For example, the following entry (one line) calls <code>bpdynamicclient</code> at seven minutes after each hour:

```
7 * * * * /usr/openv/netbackup/bin/bpdynamicclient
-last_successful_hostname
/usr/openv/netbackup/last_successful_hostname
```

For DHCP, an acceptable interval to use between calls to <code>bpdynamicclient</code> is one-half of the lease period.

About busy file processing on UNIX clients

Busy file processing applies only to UNIX clients.

Information about VSP (Volume Snapshot Provider) is available for Windows clients.

See the NetBackup Administrator's Guide, Volume I.

A busy file is a file that was detected as changed during a user or a scheduled backup. Typically, detection occurs if a process writes to a file while NetBackup attempts to back it up.

The following conditions result in the detection of busy files:

- Read error on the file
- File modification time changed
- File inode time changed
- File size changed

The backup usually completes with a status of 1, which indicates that the backup was partially successful. Busy file processing allows the user control the actions of NetBackup when busy files are detected.

Busy file processing can be configured in the **Busy File Settings** host properties for UNIX clients.

See the NetBackup Administrator's Guide, Volume I.

Busy file processing can also be enabled by adding the BUSY_FILE_PROCESSING option to the client /usr/openv/netbackup/bp.conf file. Then add other busy file options to control the processing of busy files. The options can exist in both the client /usr/openv/netbackup/bp.conf file and a user's \$HOME/bp.conf. The user's bp.conf file takes precedence when the options are in both places.

NetBackup creates several files and directories when it processes busy files. Initially, a working directory named <code>busy_files</code> is created under <code>/usr/openv/netbackup</code>. NetBackup then creates the <code>/actions</code> directory under <code>busy_files</code> and places <code>action</code> files in that directory. An action file contains the information that NetBackup uses to control the processing of busy files.

By default, the contents of the action file are derived from the <code>BUSY_FILE_ACTION</code> options in <code>bp.conf</code>. A user can also create an action file to control a specific backup policy and schedule. NetBackup creates a logs directory under <code>busy_files</code> for storing busy file status and diagnostic information.

Configuring busy file processing on UNIX

Use the following procedure to use the bp.conf file to configure busy file processing.

To configure busy file processing

1 Modify the bp.conf file options.

See "Modifying bp.conf to configure busy file processing on UNIX" on page 68.

2 Copy the bpend_notify_busy script, located on the master server:

/usr/openv/netbackup/bin/goodies/bpend_notify_busy

to the following path on the client:

/usr/openv/netbackup/bin/bpend notify

Be sure to set the file access permissions to allow groups and others to run bpend_notify.

(This step is also performed when configuring busy file processing in the **Busy File Settings** host properties.)

3 Configure a policy with a user backup schedule for the busy file backups.

This policy services the backup requests that the <code>repeat</code> option in the <code>actions</code> file generates. The policy name is significant. By default, NetBackup alphabetically searches (upper-case characters first) for the first available policy with a user backup schedule and an open backup window. For example, a policy name of <code>AAA_busy_files</code> is selected ahead of <code>B_policy</code>.

(This step is also performed when configuring busy file processing in the **Busy File Settings** host properties.)

Modifying bp.conf to configure busy file processing on UNIX

Use the following procedure to modify the ${\tt bp.conf}$ file to configure busy file processing.

To modify the <code>bp.conf</code> file to configure busy file processing

1 Configure busy file processing by using the **Busy File Settings** host properties for UNIX clients.

See the NetBackup Administrator's Guide, Volume I.

2 Or, configure busy file processing by using the entries in the bp.conf file on the client. The user can also configure a bp.conf file in a home directory. The busy file options that are specified in the user's bp.conf file apply only to user-directed backups. NetBackup ignores busy file processing for user backups if a bp.conf file does not exist in their home directory.

The bp.conf file entries to use are as follows:

- BUSY_FILE_PROCESSING
- BUSY_FILE_DIRECTORY
- BUSY_FILE_ACTION

bp.conf file entries on UNIX

The following table describes the bp.conf file entries that are used to configure busy file processing.

Entry	Description
BUSY_FILE_PROCESSING	Enables the NetBackup busy file-processing feature. By default, this entry is not present in the client's /usr/openv/netbackup/bp.conf file.
BUSY_FILE_DIRECTORY	Specifies an alternate path to the busy files working directory. This entry is not required. By default, this entry is not present in the client's /usr/openv/netbackup/bp.conf or \$HOME/bp.conf file. By default, NetBackup creates the busy_files directory in /usr/openv/netbackup or the user's home directory.

Table 2-4	bp.com me entries (continued)
Entry	Description
BUSY_FILE_ACTION	Directs the action that NetBackup performs on busy files. By default, this entry is not present in the client's /usr/openv/netbackup/bp.conf or \$HOME/bp.conf file.
	Multiple entries may exist in the following form:
	BUSY_FILE_ACTION = filename_template action_template
	Where
	 <i>filename_template</i> is the absolute pathname and file name of the busy file. The shell language metacharacters *, ?, [], [-] can be used to match the patterns of file names or parts of file names. <i>action_template</i> is one of the following:
	MAIL mail
	Directs NetBackup to mail a busy file notification message to the user that the BUSY_FILE_NOTIFY_USER option specifies.
	REPEAT repeat [repeat_count]
	Directs NetBackup to retry the backup on the specified busy file. A repeat count can be specified to control the number of backup attempts. The default repeat count is 1.
	IGNORE ignore
	Directs NetBackup to exclude the busy file from busy file processing. The file is backed up and a log entry that indicates that the file was busy appears in the All Log Entries report.
	BUSY_FILE_NOTIFY_USER
	Specifies the recipient of the busy file notification message when BUSY_FILE_ACTION is set to MAIL or mail. By default, BUSY_FILE_NOTIFY_USER is not in /usr/openv/netbackup/bp.conf or \$HOME/bp.conf file on a client. By default, the mail recipient is root.
	See Table 2-5 on page 70.

Table 2-4bp.conf file entries (continued)

The following table shows examples of how a BUSY FILE ACTIONENTRY works.

Table	2-5
-------	-----

Examples of how a BUSY FILE ACTION entry works

Example	Description
<pre>BUSY_FILE_PROCESSING BUSY_FILE_DIRECTORY = /tmp BUSY_FILE_NOTIFY_USER = kwc BUSY_FILE_ACTION = /usr/* mail BUSY_FILE_ACTION = /usr/local ignore</pre>	 This example causes NetBackup to take the following actions when it encounters busy files: Create the busy files working directory in /tmp Send an email notification message to user <i>kwc</i> for all busy files that it finds under /usr except for those in /usr/local.
BUSY_FILE_PROCESSING BUSY_FILE_ACTION = /usr/* repeat 2 BUSY_FILE_ACTION = /usr/openv mail BUSY_FILE_ACTION = /usr/local ignore	 This example causes NetBackup to take the following actions when it encounters busy files: Send a busy file notification message to root for busy files in /usr/openv. Repeat the backup up to two times for all busy files that it finds under /usr, except for those in /usr/openv and /usr/local. Exclude the busy files in /usr/local from all actions.

How NetBackup creates and uses action files on UNIX

When a backup operation begins, NetBackup creates a default action file named actions in the busy_files/actions directory. The contents of the actions file are derived from the BUSY FILE ACTION options in the bp.conf file.

Normally, NetBackup refers to the default action file for all future busy file processing. To override the default, create an action file to control a specific backup policy and schedule. The following entries show the naming convention for the policy and the schedule action files:

```
actions.policy_name.schedule_name
actions.policy_name
```

Where *policy_name* and *schedule_name* correspond to a predefined backup policy and schedule.

NetBackup performs the following steps when it searches for an action file.

Step	Example
Checks for a file that names a specific policy and schedule, such as:	actions.policy_name.schedule_name
If a file for a specific policy and schedule is not found, NetBackup searches for a less specific name, such as the following:	action <i>policy_names</i>
If a less specific name does not exist, NetBackup refers to the default action file. The contents of user-created action files	<pre># comment_line</pre>
	filename_template action_template
	Example 1:
	The bp.conf file might contain the following:
are similar to the default.	BUSY_FILE_ACTION =
Optional comment lines can be included. The	/usr/openv mail
specification is the same as for the BUSY_FILE_ACTION option:	BUSY_FILE_ACTION = /usr/* repeat 2 BUSY_FILE_ACTION = /usr/local ignore
	If yes, the default actions file (named actions) contains the following lines:
	/usr/openv mail
	/usr/* repeat 2 /usr/local ignore
	-
	Example 2:
	An action file name for a backup policy production_servers with a schedule name full follows:
	actions.production_servers.full
	The actions file can contain the following line:
	/bin/* repeat
	If yes, NetBackup repeats the backup for busy files in the $/{\tt bin}$ directory.

 Table 2-6
 NetBackup steps when it searches for an action file

About the logs directory on UNIX

During busy file processing NetBackup creates a number of files under the busy_files/logs directory. These files contain status and diagnostic information. NetBackup derives the names of these files from the policy name, schedule name, and process ID (PID) of the backup.

NetBackup creates the following logs:

Busy file log

NetBackup records the names of any busy files in the busy file log. The name of the busy file log has the following form:

policy_name.schedule_name.PID

Diagnostic log file

NetBackup generates a log file that contains diagnostic information. The name of the log file has the following form:

log.policy_name.schedule_name.PID

Retry log file

NetBackup also generates a retry file that contains diagnostic information that is recorded when the repeat option is specified. The name of the retry file has the following form:

policy_name.schedule_name.PID.retry.retry_count

Where *retry_count* starts at zero and increases by one every time a backup is repeated. Processing stops when *retry_count* is one less than the number that is specified by the repeat option.

Example:

To service busy file backup requests, the administrator defined a policy named AAA_busy_files that has a user backup schedule named user. A scheduled backup is initiated with the policy named production_servers, schedule named full, and PID of 1442.

If busy files are detected, NetBackup generates the following files in the /usr/openv/netbackup/busy files/logs directory:

```
production_servers.full.1442
log.production servers.full.1442
```

If the actions file has the repeat count set to 2, NetBackup generates the following files:

```
production_servers.full.1442.retry.0
AAA_busy_files.user.10639
log.AAA busy files.user.10639
```

If a repeat backup is attempted, NetBackup generates the following files:

```
production_servers.full.1442.retry.1
    AAA_busy_files.user.15639
    log.AAA busy files.user.15639
```

Recommended changes for modifying bpend_notify_busy on UNIX

The administrator can modify busy file processing by changing the <code>bpend_notify_busy script</code>.

The only recommended changes are as follows:

- Changing the RETRY_POLICY and RETRY_SCHED variables from NONE to the busy file backup policy name and schedule name.
- Remove the files in the logs directory after busy file processing (these logs are not removed automatically):
 - At the end of the busy_files() function, add the following command:

/bin/rm -f \$LOG_FILE

After the call to the busy_files() function in main, add the following commands:

/bin/rm -f \$BUSYFILELOG /bin/rm -f \$RETRY FILE

About specifying the locale of the NetBackup installation

NetBackup applications can display a wide range of international date and time formats as determined by the locale of the installation. To help ensure consistency among the applications, NetBackup uses a single, configurable source to define the locale conventions.

The *install_path*\VERITAS\msg\LC.CONF file (on Windows) and the /usr/openv/msg/.conf file (on UNIX) contain information on the supported locales. These files define the date and the time formats for each supported locale. The

.conf file and the LC.CONF file contain very specific instructions on how to add or modify the list of supported locales and formats.

The .conf file and the ${\tt LC.CONF}$ file are divided into two parts, the TL lines and the TM lines:

TL Lines

The third field of the TL lines defines the case-sensitive locales that the NetBackup applications support. The fourth and the fifth fields define the date and the time fields and associated separators for that supported locale. Modify the existing formats to change the default output. For example, the TL line for the C locale is the following:

TL 1 C :hh:mn:ss/mm/dd/yyyy

An alternate specification to the order of months, days, and years is as follows:

```
TL 1 C :hh:mn:ss -yyyy-mm-dd
```

Or:

TL 1 C :hh:mn:ss/dd/mm/yy

To add more TL lines, see the comments in the .conf file. If the .conf file is not accessible, the default locales (TL lines) are:

```
TL 1 C :hh:mn:ss /mm/dd/yyyy
TL 2 ov :hh:mn:ss/mm/dd/yyyy
```

Note that c and ov are synonymous.

TM Lines

The TM lines define a mapping from unrecognized locales to those supported by NetBackup, as defined by the TL lines.

The third field of the TM lines defines the unrecognized locale. The fifth field defines the supported equivalent that is identified in the TL lines.

For example, use the following TM line to map the unrecognized locale French to the supported locale fr, the TM line is:

```
TM 6 french 2 fr
```

To map French to C

```
TM 6 french 1 C \,
```

To add more TM lines, see the specific instructions in the .conf file.

If the .conf file is not accessible, no default TM lines exist as the default locale is C (ov).

About the Shared Storage Option

The Shared Storage Option allows multiple NetBackup media servers to share individual tape drives (standalone drives or drives in a robotic library). NetBackup automatically allocates and unallocates the drives as backup and restore operations require.

The Shared Storage Option is a separately licensed and a separately purchased NetBackup software option that allows tape drive sharing. The license is the Shared Storage Option key.

The Shared Storage Option is required only if multiple hosts share drives. For example, multiple NDMP hosts may share one or more drives.

The Shared Storage Option requires appropriate hardware connectivity, such as Fibre Channel hubs or switches, SCSI multiplexors, or SCSI-to-fibre bridges.

You can use Shared Storage Option in the following environments:

- Fibre Channel SANs
- Environments that do not use Fibre Channel, such as SCSI switches or multi-initiator configurations

About Shared Storage Option components

The NetBackup Enterprise Media Manager (EMM) service manages media information. The Enterprise Media Manager also is the device allocator (DA) for shared drives.

Figure 2-3 shows an example of a shared drive configuration.

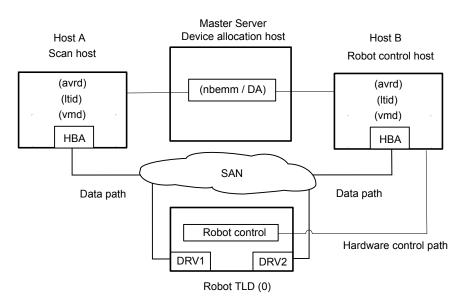

Figure 2-3 Shared Storage Option example

The following items describe the NetBackup components for the Shared Storage Option example in Figure 2-3.

 The master server hosts the Enterprise Media Manager (EMM) service. It's the device allocation host.

See About the device allocation host.

- Host A:
 - Is a NetBackup media server that runs the Automatic Volume Recognition (avrd) process, the NetBackup Device Manager service (ltid), and the NetBackup Volume Manager (vmd) service.
 - Is connected to drives DRV1 and DRV2 through SAN hardware.
 - Is the first host in the environment to come online with a non-zero scan ability factor. Therefore, it's the initial scan host for its drives.
 See About scan hosts.
- Host B:
 - Is a NetBackup media server that runs the Automatic Volume Recognition (avrd) process, the NetBackup Device Manager service (ltid), and the NetBackup Volume Manager (vmd) service.
 - Is connected to drives DRV1 and DRV2 through SAN hardware.

 Controls the robotics. Except for ACS or TLM robot types, only one robot control host exists for each robot.

For a process flow diagram of Shared Storage Option components, see the *NetBackup Logging Reference Guide*:

http://www.veritas.com/docs/DOC5332

About the device allocation host

The NetBackup Enterprise Media Manager (EMM) service allocates devices for Shared Storage Option jobs and tasks. The EMM service runs on the NetBackup master server. The host that allocates devices is also known as the device allocation host.

About SSO and the NetBackup EMM service

To coordinate network-wide allocation of tape drives, the NetBackup Enterprise Media Manager (EMM) service manages all shared tape requests in a shared drive environment. EMM responds to requests from a single NetBackup master server for its corresponding media servers, and NetBackup SAN media servers within a single NetBackup domain.

EMM maintains shared drive and host information. Information includes a list of hosts that are online and available to share a drive and which host currently has the drive reserved. The Media Manager device service (ltid) requests shared drive information changes.

About scan hosts

Scan hosts are a component of the NetBackup Shared Storage Option.

Each shared drive has a host that is identified as the scan host. A scan host is the host from which the automatic volume recognition process (avrd) scans unassigned drives. (The robotic daemons scan assigned drives.) A scan host must have data path access to the drive.

The EMM database contains the shared drive information; that information includes the scan host. Media servers receive drive status information from the EMM service.

How the scan host is determined	EMM determines scan hosts; a scan host may be different for each shared drive. The first host in the environment to come online with a non-zero scan ability factor is the initial scan host for its drives.
	To configure the scan ability factor of media servers, use the nbemmemd command. For more information, see the <i>NetBackup Commands Reference Guide</i> , available at the following URL:
	http://www.veritas.com/docs/DOC5332
The scan host can change	A scan host is assigned for a shared drive until some interruption occurs.
	For example, if one of the following occurs, EMM chooses a new scan host:
	 The socket connection, the host, the drive, the drive path, or the network goes down. The drive is logically placed in the Down mode.
	The scan host temporarily changes to hosts that request tape mounts while the mount is in progress. Scan host changes occur so only one host at a time has access to the drive path.
Drive paths for the scan host	If a drive has multiple paths that are configured on the selected scan host, EMM selects a scan path as follows:
	 The first local device path it finds in its database in the UP state. The first NDMP-attached drive path it finds in its database in the UP state.

Shared tape drive polling For shared tape drives, only the scan host polls drives until a mount request is received from NetBackup. During a mount request, NetBackup uses the host that requests the mount to poll the shared drive.

This design enables NetBackup to support Dynamic Loop Switching or SAN zones. Each tape drive needs to be detected only from a single host. Each tape drive can potentially have its own scan host that switches dynamically to process errors and continue availability. A central device arbitrating component manages scan host assignments for shared drives. The arbitrating component also provides a network drive reservation system so that multiple NetBackup media servers can share a drive.

Polling a shared tape drive allows dynamic loop switching and reduces the number of device accesses and reduces CPU time. However, it cannot detect connectivity breaks (for example, discontinuity in the Fibre Channel fabric) until I/O occurs.

About SAN media servers

SAN media servers are NetBackup media servers that back up their own data. SAN media servers cannot back up the data that resides on other clients.

SAN media servers are useful for certain situations. For example, a SAN media server is useful if the data volume consumes so much network bandwidth that it affects your network negatively.

When you define a backup policy for a SAN media server, add only the SAN media server as the client.

The NetBackup Shared Storage Option can use NetBackup SAN media servers.

About reserving or releasing shared devices

The Shared Storage Option does not load firmware in SAN devices or communicate with hub or switch APIs. The Shared Storage Option can communicate with hub or switch APIs if you use the NetBackup shared drive notify script.

NetBackup runs the shared_drive_notify script when a shared drive is reserved or released.

The script requires the following parameters:

- The name of the shared drive.
- The name of the current scan host.

• The operation, which is one of the following:

RESERVED	The host on which the script is executed needs SCSI access to the drive until it's released.
ASSIGNED	Informational only. It does not change the fact that the host that reserved the drive needs SCSI access.
RELEASED	Only the scan host needs SCSI access to the drive.
SCANHOST	The host that executes the script has become the scan host. A host should not become a scan host while the drive is RESERVED.
	The scan host may change between a RESERVED operation and a RELEASED operation.

The shared drive notify script resides in the following directory:

- On Windows: install_path\VERITAS\Volmgr\bin
- On UNIX/Linux: /usr/openv/volmgr/bin/shared drive notify

Note: The script must be executable by the root user.

The script exits with status 0 upon successful completion.

How to share robotic libraries without using the Shared Storage Option

You can share robotic tape libraries among multiple NetBackup media servers by using any of the following methods:

Shared library support

NetBackup allows different drives within the same robotic library to be configured on different media servers. This capability is termed shared library support. Robot types that support shared library are ACS, TL8, TLD, TLH, TLM.

Partitioned libraries

Some robot vendors also let you partition libraries. One partitioned view of the robotic library includes one set of drives, while the other view has a different set of drives in the library. Partitions let two robotic control daemons on different control hosts manage the robotic library — possibly each for a different NetBackup master and media server environment.

These capabilities are not related to the Shared Storage Option and should not be confused with the Shared Storage Option.

Shared Storage Option terms and concepts

 Table 2-7 describes the terms and the concepts relevant to understanding the

 Shared Storage Option.

Term	Definition
Backup Exec Shared Storage Option	The NetBackup Shared Storage Option is not the same as the Veritas Backup Exec Shared Storage Option. The Backup Exec SSO does not include support for UNIX servers and uses a different method for drive arbitration.
SAN media servers	A NetBackup SAN media server backs up its own data to shared drives. It cannot back up data on other NetBackup hosts or clients. Veritas licenses NetBackup SAN media servers.
Shared drive	When the Shared Storage Option is installed, a tape drive that is shared among hosts is termed a shared drive. For the drives that are attached to NDMP hosts, each NDMP attach host is considered an additional host.

 Table 2-7
 Shared Storage Option terms and concepts

About the Shared Storage Option license

The Shared Storage Option is a feature that is licensed separately from base NetBackup. The NetBackup Shared Storage Option license is based on the number of physical tape drives to share. The license activates NetBackup to share the specific number of physical drives for which you are licensed.

About Shared Storage Option prerequisites

To configure your hardware for use with Shared Storage Option, you must ensure that the following prerequisites are satisfied:

- Configure your SAN environment.
- Attach robots and drives.
- Ensure that all of the servers recognize the shared devices. Device recognition
 may depend on operating system configuration, as follows:
 On UNIX or Linux conversion may have to modify configuration files such as

On UNIX or Linux servers, you may have to modify configuration files, such as the sg driver on Solaris systems.

On Windows servers, Windows recognizes devices automatically. However, in some instances you may have to install device drivers.

Some of the following tasks may be optional depending on your hardware:

- Determine the physical location of each drive within the robot. Location usually is shown on the connectors to the drives or in the vendor documentation. This task may not be required if NetBackup device discovery accurately determines drive location within the robot.
- Connect all drives and all robots.
- Install SAN connecting hardware (for example, bridges, switches, or hubs).
- If fiber is part of your configuration and you use a SCSI-to-fiber bridge, determine the SCSI-to-Fibre Channel mapping for your tape devices.
 Hard-wired SCSI IDs are converted to Fibre Channel logical unit numbers (LUNs) that the hosts read. To ensure correct drive assignments, you should know which LUNs map to which physical SCSI IDs. Use persistent LUN mapping if possible.

Familiarity with the hardware and various vendor configuration tools help you accomplish this task. See the vendor documentation for your bridge.

• Record the physical configuration.

When you set up a Shared Storage Option configuration, record your hardware information. Record the adapter, SCSI addresses, World Wide Names (WWNs), and Fibre Channel LUNs to which you connected each drive. Also, record the version levels of firmware and drivers.

- Install and configure the appropriate drivers. See your vendor documentation for instructions.
- On UNIX and Linux servers, create any device files that are needed. Depending on the operating system, a reconfiguration system start (boot -r) may create these files automatically.

Create the device files for each drive; use the Fibre Channel LUNs of the drives and adapters in the device file names. Add the names of the device files to your notes to complete the correlation between device files and physical drive location. Use the *NetBackup Device Configuration Guide* and the man pages that are available with the operating system.

See the *NetBackup Device Configuration Guide*, available at the following URL: http://www.veritas.com/docs/DOC5332

 On UNIX and Linux servers, customize the operating system by modifying the appropriate system configuration files. This task requires knowledge of the system files that use the Shared Storage Option environment and their formats. For example, on Sun Solaris systems you may need to modify the sg, st, and HBA driver files.

Modify the HBA driver files to bind Fibre Channel devices (WWN) to a specific target ID. For procedures, see the operating system documentation.

- For instructions on how to configure the HBA on Windows servers, see the HBA documentation from the vendor.
- Use any available hardware configuration interface to configure and ensure that the configuration is what you expect. For example, on Windows servers you can use the Hyperterminal interface to configure SCSI-to-fibre bridges.

Use the following order when you configure and verify the hardware:

- Robot and shared drives
- Bridges
- Hub or switches
- Hosts
- If errors occur and you suspect the operating system, refer to the operating system logs as described in your operating system documentation.

About hardware configuration guidelines

The following are hardware configuration guidelines:

- If you use SAN hardware from multiple vendors, problems may occur. Always use a SAN configuration and use the firmware levels that the hardware vendor supports.
- Consult SAN device, HBA, and operating system documentation to determine how to configure operating system tape drivers and pass-through drivers to detect your SAN devices.
- Check your hub timer settings.
- Use hard arbitrated loop physical addresses rather than soft addresses. Consult
 with hardware suppliers to verify the recommended usage of their products.
- Check the firmware levels of all your Fibre Channel hardware (for example, bridges). Use the most recent firmware level that is known to operate with other SAN hardware devices.
- Try to duplicate SAN issues and problems using commands and utilities on the host operating system.
- Test both backup and restore capabilities. Backup jobs may complete successfully, but the data may be corrupted. For example, incorrect switch settings may cause problems.
- Ensure that your hardware and SAN configuration are operational and stable before adding Shared Storage Option software.

- Test backup and restore capabilities with dedicated tape drives before you configure them as shared drives.
- For large configurations, begin drive sharing with a few tape drives and two or three media servers (or NetBackup SAN media servers).
- Configuration and troubleshooting processes are easier on smaller configurations.
 If possible, create multiple and independent Shared Storage Option configurations with subsets of servers sharing subsets of SAN-attached drives.
- Use the correct start order for your Fibre Channel hardware, as follows:
 - Robots or drives
 - Bridges
 - Hubs or switches
 - Hosts
- The start sequence is longer for some devices than others. To verify that the hardware starts completely, examine indicator lights. A green light often indicates a completed start sequence.

About installing and configuring drivers

On the media server systems, install and configure drivers and modify the appropriate system configuration files.

Guidance about the NetBackup requirements is available.

See the NetBackup Device Configuration Guide, available at the following URL:

http://www.veritas.com/docs/DOC5332

Verifying the connectivity

Test your hardware configuration before you configure Shared Storage Option in NetBackup. This task is very important and is often overlooked.

Note the following points:

- Verify that all of your servers (master and media) can communicate with one another. To do so, use the ping command from each server to every other server. Be sure to ping by host name to verify that the name resolution methods function properly.
- Use the NetBackup bpclntcmd utility to resolve IP addresses into host names.
 For more information, see the NetBackup Troubleshooting Guide and the NetBackup Commands Reference Guide, available through the following URL: http://www.veritas.com/docs/DOC5332

 Use operating system and NetBackup commands and tools to verify that the devices are configured correctly. Make sure that the operating system detects the devices on the SAN before you configure the Shared Storage Option. If the configuration does not work in the operating system, it does not work for the Shared Storage Option.

For example, on Solaris systems you can use the mt - f tapename status command to determine tape drive status.

 For more information and examples, see the appropriate operating system chapter in the *NetBackup Device Configuration Guide*, available at the following URL:

http://www.veritas.com/docs/DOC5332

About configuring the Shared Storage Option in NetBackup

You must configure your shared drives, storage units, and backup policies.

About configuring SSO in NetBackup	See "About configuring SSO in NetBackup" on page 85.
Configuring Shared Storage Option devices in NetBackup	See "Configuring Shared Storage Option devices in NetBackup" on page 86.
About adding Shared Storage Option configuration options	See "Configuring Shared Storage Option devices in NetBackup" on page 86.
About configuring NetBackup storage units and backup policies	See "About configuring NetBackup storage units and backup policies" on page 86.

About configuring SSO in NetBackup

Veritas recommends that you use the Device Configuration Wizard to configure Shared Storage Option in NetBackup. Identifying devices when you configure shared devices is difficult, and the wizard increases the likelihood of a successful configuration.

With the Device Configuration Wizard, you should configure all shared drives from one host (usually the master server). Launch the wizard only one time with the current host set to the master server. You then indicate a list of media servers or NetBackup SAN media servers (in the Device Hosts screen). The wizard configures devices on all of the media servers you selected, and these hosts read the shared configuration information.

Configuring Shared Storage Option devices in NetBackup

Veritas recommends that you use the **Device Configuration Wizard** to configure shared drives. The wizard guides you through the steps to configure shared drives.

Be sure to review the limitations of the wizard in the wizard help.

To start the Device Configuration Wizard

- 1 In the NetBackup Administration Console, expand Media and Device Management.
- 2 Click Configure Storage Devices.

Note: You must restart the NetBackup Device Manager (Itid) on all the servers that share tape drives whenever you perform the following actions:

- Configure the shared drives to a newly added media server.

- Add or remove the shared drives paths.

About adding Shared Storage Option configuration options

You can fine-tune your configuration by adding Shared Storage Option options to the vm.conf Media Manager configuration file.

See "About the vm.conf configuration file" on page 96.

About configuring NetBackup storage units and backup policies

You must configure storage units and policies for your shared drives. If you used the **Device Configuration Wizard** to configure the shared drives, you may have configured storage units and policies already.

Configure storage units and backup policies as follows:

Configuring storage units for each media server In each storage unit definition, logically define the robot and the shared drives for that media server. For the **Maximum concurrent drives** used for backup, specify the total number of all shared drives in the robot. When you configure storage units, select a single media server. Alternatively, you can allow NetBackup to select the media server to use at the time of the backup. For example, you can configure a single storage unit that any media server that shares the storage unit can use. Configuring a backup policyHow you define a policy for a media server depends on yourfor each media servermedia server license, as follows:

- For a media server that is licensed for Shared Storage Option, the policy can back up the media server and any other NetBackup clients.
- For a NetBackup SAN media server, only the SAN media server can be backed up.

A license for a regular media server provides the greatest flexibility; a license for a NetBackup SAN media server is more restrictive.

For a policy for the clients that you want to back up anywhere in your configuration, you can choose any available storage unit. Alternatively, you can use storage unit groups (prioritized storage units).

For more information, see the NetBackup Administrator's Guide, Volume I:

http://www.veritas.com/docs/DOC5332

Verifying your Shared Storage Option configuration

In a Shared Storage Option configuration, a shared drive must have the same logical name (drive name) on all of the NetBackup media servers. If the drive resides in a robotic library, it also must use the same drive number in the library. This section describes some tools you can use to verify your configuration.

How you verify that your configuration is set up correctly depends on your devices and how you configured Shared Storage Option, as follows:

- If you have serialized devices, Veritas recommends that you use the Device Configuration Wizard. The wizard verifies your configuration.
- If you have non-serialized devices, see the Veritas support site for tech note TECH31764, "Verifying a Shared Storage Option (SSO) Configuration with Non-Serialized Devices. It describes how to verify your configuration.
- If you have serialized devices but you did not use the Device Configuration Wizard, use the following procedure to verify your configuration.

The verification procedures use the following NetBackup commands:

On Windows:

install_path\VERITAS\Volmgr\bin\scan
install path\VERITAS\Volmgr\bin\tpconfig

On UNIX/Linux:

```
usr/openv/volmgr/bin/scan
usr/openv/volmgr/bin/tpconfig
```

In the following example the ADIC robotic library has six drives, but only drives 5 and 6 are configured on this particular host.

Perform the verification on all of the NetBackup servers in your configuration. Ensure that each shared drive has the same logical drive name and same drive number ID on each media server that shares the drive.

To verify a manually-configured Shared Storage Option configuration

1 Execute tpconfig -d or tpconfig -dl. For NDMP devices, use tpautoconf -probe -ndmp_host_name host_list.

The output from tpconfig shows the logical names NetBackup assigns to tape drives. The following example shows drive number 5 is named QUANTUM.DLT7000.000 and drive number 6 is named QUANTUM.DLT7000.001:

Id	DriveName	Туре	Reside	nce	
	Drive Path				Status
* * * * *	* * * * * * * * * * * * * * * * * * * *	******	* * * * * * *	* * * * * * * * * * * * * * * * * * *	* * * * *
0	QUANTUM.DLT7000.000	dlt	TLD(0)	DRIVE=5	
	/dev/st/nh3c0t510)			UP
1	QUANTUM.DLT.7000.001	dlt	TLD(0)	DRIVE=6	
	/dev/st/nh3c0t110				UP
Curre	ntly defined robotics	are:			
TLD	(0) robotic path	= /dev/s	g/h3c0t	010	
EMM s	erver = norway				

2 Execute the scan command. The scan output shows the robot and the drive properties.

The following is example output:

****** Device Name : "/dev/sg/h3c0t010" Passthru Name: "/dev/sg/h3c0t010" Volume Header: "" Port: -1; Bus: -1; Target: -1; LUN: -1 Inquiry : "ADIC Scalar 100 3.10" Vendor ID : "ADIC " Product ID : "Scalar 100 " Product Rev: "3.10" Serial Number: "ADIC009K0340314" : "" WWN WWN Id Type : 0 Device Identifier: "" Device Type : SDT CHANGER NetBackup Robot Type: 6 Removable : Yes Device Supports: SCSI-2 Number of Drives : 6 Number of Slots : 50 Number of Media Access Ports: 10 Drive 1 Serial Number : "PXB03S0979" : "PXB03S0913" Drive 2 Serial Number Drive 3 Serial Number : "CXA04S2051" Drive 4 Serial Number : "PXA31S1787" Drive 5 Serial Number : "PXA37S3261" Drive 6 Serial Number : "PXA50S2276" Flags : 0x0 Reason: 0x0 _____ Device Name : "/dev/st/nh3c0t510" Passthru Name: "/dev/sg/h3c0t510" Volume Header: "" Port: -1; Bus: -1; Target: -1; LUN: -1 2561" Inquiry : "QUANTUM DLT7000 Vendor ID : "QUANTUM " Product ID : "DLT7000 "

Device Supports: SCSI-2
Flags : 0x4
Reason: 0x0
```

- **3** For each tape drive in the tpconfig output, do the following:
 - Use the device file name from the tpconfig output to locate the tape drive in the scan output.
 Step 1 shows device file pathnames /dev/st/nh3c0t510 and /dev/st/nh3c0t110.
 - Determine the serial number of the drive in the scan output. "Tape" in the device type field identifies a tape drive.
 Step 2 shows example scan output shows the following:
 The drive /dev/st/nh3c0t510 serial number is PXA37S3261.
 The drive /dev/st/nh3c0t110 serial number is PXA50S2276.

 Verify that the serial number for the drive matches the serial number in the output from the robot section of scan. "Changer" in the device type field identifies a robot.

In the previous examples, the serial numbers match.

Device Monitor and Shared Storage Option

You can use the **Device Monitor** in the **NetBackup Administration Console** to obtain information about your Shared Storage Option configuration and manage your shared drives. See the following:

For more information about the Device Monitor, see the *NetBackup Administrator's Guide, Volume I*:

http://www.veritas.com/docs/DOC5332

Table 2-8 describes information you can glean from the **Device Monitor**.

Action	Information
Drive Status pane	The Control and Device Host columns contain shared drive information.
Changing the operating mode for a shared drive	For a shared drive, the Change Mode dialog contains a list of all paths to the selected drive. You can choose any number of paths to which the mode change applies.
Adding or changing a comment for a shared drive	For a shared drive, the Change Drive Comment dialog box contains the following:
	 A list of all paths to the selected drive
	The current drive comment for each combination.
	You can choose any number of paths to which the changes apply.
Performing drive cleaning functions for a shared drive	The three available drive cleaning functions are used with shared drives are as follows:
	■ Clean Now
	In the list of hosts that share the drive, you can choose only one host on which the function applies.
	 Reset Mount Time
	In the list of hosts that share the drive, you can choose any number of hosts on which the function applies.
	 Set Cleaning Frequency
	Supported for shared drives.

 Table 2-8
 Device Monitor information

Viewing SSO summary reports

You can view Shared Storage Option Summary reports.

See "Shared Storage Option summary reports" on page 93.

To view SSO summary reports

- 1 In the NetBackup Administration Console, in the left pane, expand Media and Device Management > Device Monitor.
- 2 On the Actions menu, select View Status of Shared Drives.
- 3 In the Status of Shared Drives dialog box, select a device allocation host (or hosts) from the list.
- 4 Use Add to move the host to the list of hosts to scan.
- 5 Click OK.

The **Shared Drive Summary** and **Device Allocation Host Summary** appear in the two lower panes of the dialog.

Shared Storage Option summary reports

The following two reports contain the following information about the drives and hosts:

- The Shared Drive Summary shows the following:
 - Drive name
 - Device allocation host
 - Number of registered hosts
 - Drive reservation status
 - Hosts that reserve the drive
 - Current scan host
- The Device Allocation Host Summary shows the following:
 - Device allocation host
 - Host name of the registered host
 - Number of registered and reserved drives
 - Availability status
 - Scan ability factor
 - Scan status (if the host is scan host for at least one SSO drive)

Operating system assistance

If errors occur during the installation or configuration of the shared devices and you suspect problems with the operating system, refer to the following:

- Operating system logs, as described in the operating system documents.
- NetBackup logs.
- Operating system man pages (UNIX or Linux servers only).
- The NetBackup Device Configuration Guide, available at the following URL: http://www.veritas.com/docs/DOC5332

Common configuration issues with Shared Storage Option

If you cannot obtain full functionality after you configure SSO, consider the following:

- Verify that the SAN hardware uses current firmware or drivers. Hardware includes hubs, switches, HBAs, and bridges.
- Verify that the JNI HBA failover value was set to zero to avoid I/O hangs. This
 value applies to bridges and HBAs.
- Verify that the HBAs with the SCSI-3 protocols are compatible with the operating system drivers.
- Verify that your cluster configuration is supported.
 For more information about cluster configuration, see the NetBackup Release Notes, available at the following URL: http://www.veritas.com/docs/DOC5332
- Verify that all of your Fibre Channel devices support your Fibre Channel topology.
 For example, in a switched fabric topology, ensure that all devices supported switched fabric.
- Verify that Shared Storage Option is licensed on each server. To do so, select Help > License keys from the NetBackup Administration Console on each server. To enable the Shared Storage Option, enter the Shared Storage Option license on each server.
- Verify that you configured Shared Storage Option from the master server. You
 must configure SSO from the master server not from a media server (or SAN
 media server).
- Verify that you configured the same robot control host on every host. Remember that except for ACS and TLM robot types, only one host controls the robot.
- Verify that you used the Device Configuration Wizard rather than the tpconfig utility to configure Shared Storage Option. The wizard coordinates configuration

with all hosts that share the drives. The tpconfig utility may create inconsistent configurations.

- Verify that you selected the appropriate device hosts in the Device Configuration Wizard, including the host with robotic control.
- Fibre Channel connections to the drives and the robots cause increased complexity in a NetBackup device configuration. On some operating systems, SCSI-to-fibre bridges may result in inconsistencies in the device paths when you restart a host. After a restart of the host, the device configuration should be verified.
- Verify that names across all systems that share the drives are consistent.
- Test the drive paths on every media server.
- Define NetBackup storage units for each media server. Do not select any available media server in the storage units.
- Verify that you did not interrupt a data path during a backup. If you do, the NetBackup job fails. It can fail with media write errors or it may hang and have to be terminated manually.
- Verify that you do not use Berkeley-style close on the tape path (UNIX or Linux servers only).
- On Solaris systems, verify the following:
 - That you added tape configuration list entries in /kernel/drv/st.conf (if needed).
 - That you defined configuration entries for expanded targets and LUNs in sg.links and sg.conf files. If you see problems with the entries in the /etc/devlink.tab file (created from sg.links), verify the following:
 The first entry uses hexadecimal notation for the target and LUN. The second entry uses decimal notation for the target and LUN.
 Use a single tab character between the entries; do not use a space or a space and a tab character.
 - That you configured the operating system to force load the sg/st/fcaw drivers.

For more information, see the Solaris chapter of the *NetBackup Device Configuration Guide*, available at the following URL: http://www.veritas.com/docs/DOC5332

Frequently asked questions about Shared Storage Option

Q. What combinations of SAN hardware components are supported for Shared Storage Option?

A. Shared Storage Option works with many hardware combinations. Veritas has an open policy on hardware support for Shared Storage Option. Consult your hardware suppliers to verify the interoperability of their products.

A list of SAN components that have been tested with NetBackup is available on the Veritas support Web site:

http://www.netbackup.com/compatibility

Q. If NetBackup allocates four drives to a server and it finishes with two of the drives, does NetBackup reallocate the two drives? Or does NetBackup wait until the backup schedule that uses the four drives is completely finished before it reallocates the drives?

A. The two available drives are reallocated and used. NetBackup monitors drive status and notifies the NetBackup scheduler of drive availability.

Q. Does NetBackup Shared Storage Option use the IP protocol or the SCSI protocol?

A. Both. IP protocol is used to provide coordination between servers. Shared Storage Option uses SCSI protocol (SCSI reserve) as an added layer of protection.

About the vm.conf configuration file

The vm.conf file contains configuration entries for media and device management. NetBackup can create this file, but if it does not exist, you must create it.

On Windows, the pathname is *install_path*\Volmgr\vm.conf.

On UNIX, the pathname is /usr/openv/volmgr/vm.conf.

Various NetBackup components read this configuration file on the host where the component runs. The NetBackup component is a command, daemon, process, or utility. The host can be a NetBackup administration client or a server where administration operations are requested.

See "Example vm.conf file" on page 113.

ACS_mediatype entry in vm.conf

The following configuration entry applies to NetBackup servers:

ACS_mediatype = Media_Manager_mediatype

If this entry is used in vm.conf, the ACS media type is mapped to the specified Media Manager media type. More than one $ACS_mediatype$ entry can be specified.

This entry is read and interpreted on the host on which <code>vmcheckxxx</code> and <code>vmupdate</code> run during a robot inventory operation. Use this entry on every NetBackup media server that functions as an ACS robot control host.

A list of the valid ACS mediatype entries is available.

See the NetBackup Administrator's Guide, Volume I:

http://www.veritas.com/docs/DOC5332

ACS_SEL_SOCKET entry in vm.conf

The following configuration entry applies to NetBackup servers:

ACS SEL SOCKET = socket name

By default, <code>acssel</code> listens on socket name 13740. If this entry is specified in <code>vm.conf</code>, the default can be changed. This entry is read and interpreted on the host on which <code>acsd runs</code>.

ACS_CSI_HOSTPORT entry in vm.conf (on UNIX)

The following configuration entry applies to NetBackup servers:

ACS CSI HOSTPORT = ACS library software hostname socket name

The valid value for ACS_library_software_hostname is the host name of the ACS library host. Do not use the IP address of the ACS library host for this parameter.

The valid values for *socket_name* are 1024 - 65535 and 0. The value must match the value on the ACSLS server for the port that the CSI uses for inbound packets.

If 0 (zero), NetBackup uses the previous behavior of CSI and acssi (no specific ports).

This entry specifies the port where the acssi process sends its ACSLS requests on the ACSLS server. The ACSLS CSI must use this port to accept inbound ACSLS requests from acssi processes.

This entry, the <code>ACS_SSI_INET_PORT</code> entry, and the <code>ACS_TCP_RPCSERVICE</code> entry are commonly used with firewall implementations. With these three entries in the <code>vm.conf</code> file, TCP connections use the designated destination ports. Note that TCP source ports are not restricted.

See "ACS_SSI_INET_PORT entry in vm.conf (on UNIX)" on page 98.

See "ACS_TCP_RPCSERVICE / ACS_UDP_RPCSERVICE entry in vm.conf (on UNIX)" on page 99.

For example, a NetBackup media server has two ACSLS servers (ACSLS_1 and ACSLS_2) behind firewalls. Both servers listen for queries on port 30031 and the firewall allows traffic through this port.

The vm.conf entries are as follows:

ACS_TCP_RPCSERVICE ACS_CSI_HOSTPORT = ACSLS_1 30031 ACS_CSI_HOSTPORT = ACSLS_2 30031 ACS_SSI_INET_PORT = ACSLS_1 30032 ACS_SSI_INET_PORT = ACSLS_2 30033

Each acsssi process sends queries to the respective ACSLS server's port 30031, and the ACSLS server is configured to listen for queries on this port.

ACS_SSI_HOSTNAME entry in vm.conf

The following configuration entry applies to NetBackup servers:

ACS SSI HOSTNAME = host

Use ACS_SSI_HOSTNAME to specify the host to which RPC return packets from ACS library software are routed for ACS network communications. By default, the local host name is used. This entry is read and interpreted on the host on which acsd and acsssi run. Do not use the IP address of the host for this parameter.

ACS_SSI_INET_PORT entry in vm.conf (on UNIX)

The following configuration entry applies to NetBackup servers:

ACS SSI INET PORT = ACS library software hostname socket name

The valid value for ACS_library_software_hostname is the host name of the ACS library host. Do not use the IP address of the ACS library host for this parameter.

The *socket_name* entry specifies the port that acssi uses for incoming ACSLS responses. Valid values are 1024 - 65535 and 0. This value must be unique for each acssi process.

A value between 1024 - 65535 indicates the number to be used as the TCP port on which acsssi accepts ACSLS responses.

0 (zero) indicates that the previous behavior (allow the port to be dynamically allocated) should remain in effect.

This entry, the <code>ACS_CSI_HOSTPORT</code> entry, and the <code>ACS_TCP_RPCSERVICE</code> entry are commonly used with firewall implementations. With these three entries in the <code>vm.conf</code> file, TCP connections use the designated destination ports. Note that TCP source ports are not restricted.

See "ACS_CSI_HOSTPORT entry in vm.conf (on UNIX)" on page 97.

See "ACS_TCP_RPCSERVICE / ACS_UDP_RPCSERVICE entry in vm.conf (on UNIX)" on page 99.

For example, a NetBackup media server has two ACSLS servers (ACSLS_1 and ACSLS_2) behind firewalls. Ports 30032 and 300033 have been opened in the firewall for acsssi to ACSLS server communication.

The entries would be as follows:

```
ACS_TCP_RPCSERVICE
ACS_SSI_INET_PORT = ACSLS_1 30032
ACS_SSI_INET_PORT = ACSLS_2 30033
ACS_CSI_HOSTPORT = ACSLS_1 30031
ACS_CSI_HOSTPORT = ACSLS_2 30031
```

The NetBackup media server starts two acssi processes. One listens for ACSLS_1 responses on port 30032, and the other listens on port 30033 for responses from ACSLS_2.

ACS_SSI_SOCKET entry in vm.conf

The following configuration entry applies to NetBackup servers:

ACS_SSI_SOCKET = ACS_library_software_hostname_socket_name

The valid value for *ACS_library_software_hostname* is the host name of the ACS library host. Do not use the IP address of the ACS library host for this parameter.

By default, <code>acsssi</code> listens on unique, consecutive socket names; the names begin with 13741. If this entry is specified in <code>vm.conf</code>, specify socket names on an ACS library software host basis. This entry is read and interpreted on the host where <code>acsd</code> and <code>acsssi</code> are running.

ACS_TCP_RPCSERVICE / ACS_UDP_RPCSERVICE entry in vm.conf (on UNIX)

The following configuration entries apply to NetBackup servers:

ACS_TCP_RPCSERVICE ACS_UDP_RPCSERVICE These entries specify the method over which acssi communicates with ACSLS servers: TCP or UDP.

Only one entry should be entered into vm.conf. NetBackup uses UDP if both entries are found or neither entry is found.

For acsssi firewall support, ACS_TCP_RPCSERVICE must be entered in vm.conf.

See "ACS_CSI_HOSTPORT entry in vm.conf (on UNIX)" on page 97.

See "ACS_SSI_INET_PORT entry in vm.conf (on UNIX)" on page 98.

ADJ_LSM entry in vm.conf

The following configuration entry applies to NetBackup servers:

ADJ_LSM = robot_num ACS_ID,LSM_ID ACS_ID,LSM_ID

In an ACS robot with multiple library storage modules (LSMs), pass-through mechanisms can move ejected media to the media access port (MAP). A pass-through mechanism passes media from one LSM to another. This travel time can be excessive when media must pass through several LSMs.

Use this entry to specify the physical orientation of the LSMs in an ACS robot. If this entry is specified in vm.conf, you do not need to know which MAP (or ACS CAP) to select for efficient ejects. NetBackup determines the appropriate MAP to complete the media eject by using a nearest-MAP algorithm.

This nearest-MAP algorithm is based on the physical orientation of the LSMs that defined with this entry. This algorithm is only for the cases where more than one MAP is requested to handle the eject. If this algorithm is used, any <code>MAP_ID</code> entries in <code>vm.conf</code> are ignored.

Note: nearest-MAP capability is only available by using the vmchange command with the -map option or the Vault administrative interface. It is not available from the **NetBackup Administration Console**.

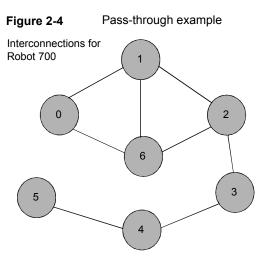

Without this entry present, NetBackup assumes that all LSMs are interconnected with pass-through ports, except for the first LSM and the last LSM. The LSMs are interconnected in a line formation.

robot_num is the robot number. *ACS_ID* and *LSM_ID* are the coordinates of the LSM.

Figure 2-4 is a diagram of LSM interconnections that are described by the following entries:

ADJ_LSM = 700 0,0 0,1 ADJ_LSM = 700 0,0 0,6 ADJ_LSM = 700 0,1 0,2 ADJ_LSM = 700 0,1 0,6 ADJ_LSM = 700 0,2 0,6 ADJ_LSM = 700 0,2 0,3 ADJ_LSM = 700 0,3 0,4 ADJ_LSM = 700 0,4 0,5

The robot has pass-through mechanisms between 7 LSMs.

API_BARCODE_RULES entry in vm.conf

The following configuration entry applies to NetBackup servers:

API_BARCODE_RULES

If this entry is specified in vm.conf, barcode rule support for API robots is enabled.

NetBackup barcode rules allow default media mappings to be overridden. Barcode rules are especially useful when multiple generations of the same tape drive use the same type of media.

For example STK 9940A and STK 9940B drives use STK1R media, but write data at different densities. The drive must be configured by using different drive types such as HCART or HCART2. Specify a barcode rule for a series of bar codes to configure some of the media as HCART2. Other STK1R media not in this barcode range are configured as HCART (the default for STK1R). Without this entry, a robot

inventory operation configures all media of type STK1R as either HCART or HCART2, depending on how the drive was configured.

AUTHORIZATION_REQUIRED entry in vm.conf

This entry specifies that NetBackup should use the vm.conf file SERVER entry to control which hosts can monitor and control devices on this host. This entry is read and interpreted on the media server on which the NetBackup vmd service runs, as follows:

AUTHORIZATION_REQUIRED

If this entry is specified in vm.conf, the vm.conf file also must include a SERVER entry for every media server that controls devices on this host.

If no AUTHORIZATION_REQUIRED entry exists and no SERVER entries exist, any NetBackup server can monitor and control devices on this host.

For maximum security, Veritas recommends that you use this entry and SERVER entries.

This entry is read and interpreted on media servers on which the NetBackup ${\tt vmd}$ service runs.

AUTO_PATH_CORRECTION entry in vm.conf

If this entry is specified in vm.conf, it specifies whether automatic device path remapping is enabled or disabled, as follows:

AUTO_PATH_CORRECTION = YES | NO

If the value is NO, the device configuration remains unchanged when the NetBackup Device Manager (ltid) is started. Therefore, the saved device configuration may be different than the actual configuration after devices are changed and the server is restarted.

If the value is YES, NetBackup tries to discover attached devices and then automatically update the device configuration for any device paths that are incorrect. This entry is read and interpreted on the host on which the NetBackup Device Manager (ltid) runs.

Device path remapping is enabled by default on Windows and Linux servers. It is disabled by default on all other servers.

AUTO_UPDATE_ROBOT entry in vm.conf

Use this entry to inject media automatically from the Media Access Port (MAP) into a TL8 or TLD robot and update the EMM database. Media are injected if the robot generates a unit attention message.

AUTO UPDATE ROBOT

This entry only operates with the TL8 or TLD robots that post a unit attention when their MAP is opened.

Veritas recommends that this entry not be used with partitioned libraries. Most robotic libraries with multiple partitions do not post a unit attention when the MAP is opened.

AVRD_PEND_DELAY entry in vm.conf

If this entry is specified in vm.conf, avrd waits *number_of_seconds* before it displays a pending status (PEND) in the Device Monitor. This entry is read and interpreted on the host on which avrd runs.

AVRD_PEND_DELAY = number_of_seconds

On some server operating systems (Windows and HP-UX), NetBackup reports PEND if the drive reports Busy when a volume is unmounted. Use this entry to minimize the display of this misleading status.

The minimum for *number_of_seconds* is zero. The maximum is 255. The default value is 180 seconds.

AVRD_SCAN_DELAY entry in vm.conf

If this entry is specified in vm.conf, avrd waits *number_of_seconds* between normal scan cycles. This entry is read and interpreted on the host on which avrd runs.

```
AVRD SCAN DELAY = number of seconds
```

Use this entry to minimize tape mount times. Without this entry, NetBackup delays mount requests by an average of 7.5 seconds.

The minimum for *number_of_seconds* is 1. The maximum is 180. A value of zero converts to one second. The default value is 15 seconds. If a value is used that is greater than the default, NetBackup delays mount requests and drive status updates in the Device Monitor.

Note: If *number_of_seconds* is set to a value that allows media to be changed within one scan cycle, NetBackup may not detect media changes. Data loss may occur.

CLEAN_REQUEST_TIMEOUT entry in vm.conf

Use this entry to specify how long NetBackup waits for a drive to be cleaned before it removes the cleaning request from the cleaning queue. Unprocessed requests to clean a drive are removed from the queue after 30 minutes.

```
CLEAN REQUEST TIMEOUT = minutes
```

The *minutes* can be from 1 to 144000 (100 days). The default value is 30 and a value of zero converts to the default value of 30.

CLIENT_PORT_WINDOW entry in vm.conf

Use this entry to specify the range of non-reserved ports on this host that are used to connect to vmd on other hosts. This entry is read and interpreted on the host on which vmd runs.

CLIENT PORT WINDOW = start end

For example, the following entry permits ports from 4800 through 5000:

CLIENT PORT WINDOW = 4800 5000

The operating system determines the non-reserved port to use in the following cases:

- A CLIENT PORT WINDOW entry is not specified.
- A value of zero is specified for start.

CLUSTER_NAME entry in vm.conf

This entry specifies the virtual name for the media server on which the vm.conf file resides.

```
CLUSTER NAME = cluster alias
```

See "Host name precedence in the vm.conf file" on page 114.

DAS_CLIENT entry in vm.conf

The following configuration entry applies to NetBackup servers:

```
DAS_CLIENT = client_name
```

If this entry is specified in vm.conf, specify the DAS client name that the TLM robot uses for communications with the DAS/SDLC server. By default, this client name is the host name of the media server. This entry is read and interpreted on the host where tlmd is running.

DAYS_TO_KEEP_LOGS entry in vm.conf

If this entry is specified in vm.conf, specify the number of days to keep debug logs before vmd deletes them. This entry is read and interpreted on the hosts where vmd is running.

```
DAYS TO KEEP LOGS = days
```

The default is 30 days. A value of zero means that the logs are not deleted. This entry does not affect the debug logs that Unified Logging creates.

Information about Unified Logging is available in the NetBackup Logging Reference Guide.

EMM_RETRY_COUNT entry in vm.conf

The vmd daemon and the ltid daemon use this entry to determine how many times to retry requests to the NetBackup Enterprise Media Manager.

```
EMM RETRY COUNT = number of retries
```

The default is one retry.

Only change the value of this vm.conf file entry when directed to do so by a NetBackup support representative. If this entry is added to the vm.conf file or if this value is changed, restart the vmd daemon and the ltid daemon.

EMM_CONNECT_TIMOUT entry in vm.conf

This value applies for broken connections between the NetBackup Enterprise Media Manager and the following daemons: the vmddaemon and the ltid daemon. These two daemons use this entry to determine for how long they should try to reconnect to the NetBackup Enterprise Media Manager.

EMM CONNECT TIMOUT = number of seconds

The default is 20 seconds.

Only change the value of this vm.conf file entry when directed to do so by a NetBackup support representative. If this entry is added to the vm.conf file or if this value is changed, restart the vmd daemon and the ltid daemon.

EMM_REQUEST_TIMOUT entry in vm.conf

The vmd daemon and the ltid daemon use this entry to determine how many seconds to allow a request to the NetBackup Enterprise Media Manager to complete.

EMM_REQUEST_TIMOUT = number_of_seconds

The default is 300 seconds.

Only change the value of this vm.conf file entry when directed to do so by a NetBackup support representative. If this entry is added to the vm.conf file or if this value is changed, restart the vmd daemon and the ltid daemon.

ENABLE_ROBOT_AUTH entry in vm.conf

Veritas encourages the use of Veritas Product Authentication and Authorization for NetBackup Access Control (NBAC) instead of legacy security implementations.

For information about the ENABLE_ROBOT_AUTH configuration entry, see the NetBackup 6.0 documentation. Information on Veritas Product Authentication and Authorization is available.

See the NetBackup Security and Encryption Guide:

http://www.veritas.com/docs/DOC5332

INVENTORY_FILTER entry in vm.conf

The following configuration entry applies to NetBackup servers:

INVENTORY_FILTER = robot_type robot_number mode value1 [value2 ...]

Used to filter the robot inventory results in ACS or TLH robot types. Add this entry to the configuration file (vm.conf) on the NetBackup server on which the inventory operation is invoked. This entry is read and interpreted on the host on which vmcheckxxx and vmupdate run.

Note: This entry may be required for an ACS robot and the ACS library software host with an STK Library Station. Newer versions of STK Library Station allow robot inventory commands to function correctly so filters are not required.

robot_type can be ACS or TLH.

robot_number is the number of the robot as was configured in NetBackup.

mode is by acs pool for ACS or by category for TLH.

See the following examples:

INVENTORY_FILTER = ACS 0 BY_ACS_POOL 4 5 INVENTORY FILTER = TLH 0 BY CATEGORY FFFA CDB0

MAP_ID entry in vm.conf

The following configuration entry applies to NetBackup servers:

MAP ID = robot num map ID

Use this entry to configure the default media access port (MAP) to use to eject media from the Automated Cartridge System (ACS) robots. This default is selected in the **NetBackup Administration Console**, but you can also select other Media Access Ports for ejects.

If the MAP is not available or the vm.comf file does not contain this entry, NetBackup uses the default MAP selection process. By default, NetBackup uses the smallest MAP that can hold the number of media to be ejected.

If NetBackup selects multiple MAPs, NetBackup uses the nearest-MAP algorithm rather than the MAP that is specified in the MAP ID entry.

See "ADJ LSM entry in vm.conf" on page 100.

robot_num is the robot number. *map_ID* is in the format of an ACS CAP (cartridge access port) ID and cannot contain any spaces.

The following example specifies the MAP ID for ACS robot number 700. The ACS CAP ID of 0,1,0 is used.

```
MAP ID = 700 0, 1, 0
```

MAP_CONTINUE_TIMEOUT entry in vm.conf

This entry applies only when the vmchange command is used and the -w option is specified.

MAP CONTINUE TIMEOUT = seconds

The default timeout value for *seconds* is 300 (5 minutes). *seconds* cannot be zero and values greater than 1200 (20 minutes) can cause the robotic daemon to cancel the operation.

If this entry is specified in vm.conf, the SCSI robotic daemons wait the specified number of seconds before they time out. A timeout can occur while the daemons

wait for user reply after the user removes volumes from the media access port. If a timeout occurs, NetBackup aborts the operation.

This entry is read and interpreted on the host on which the SCSI-controlled robotic daemon or process runs.

Note: Non-mount activities such as a robotic inventory cannot occur during this timeout period.

MEDIA_ID_BARCODE_CHARS entry in vm.conf

If this entry is specified in vm.conf, it controls the NetBackup media ID generation. This entry is read and interpreted on the host on which vmcheckxxx and vmupdate run as part of the robot inventory operation.

MEDIA ID BARCODE CHARS = robot num barcode length media ID rule

Note: To use this entry, the robot must support bar codes and the robot type cannot be an API robot.

Choose how NetBackup creates media IDs by defining the rules that specify which characters of a barcode on tape NetBackup uses. Alphanumeric characters can be specified to be inserted in the ID.

Multiple entries can be added to the vm.conf file. For example, specify media ID generation for each robot or for each barcode format that has different numbers of characters. The multiple entries allow flexibility for multimedia.

If no MEDIA_ID_BARCODE_CHARS entries exist or the entry is invalid, NetBackup uses the rightmost six characters of the barcode to create its media ID.

robot_num is the robot number.

barcode_length is the length of the barcode.

A *media_ID_rule* consists of a maximum of six fields that colons delimit. Numbers in the fields define the positions of the characters in the barcode that NetBackup extracts (from left to right). For example, if the number 2 is in a field, NetBackup extracts the second character from the barcode. The numbers can be specified in any order.

If the pound sign (#) prefixes a character, that character is inserted in that position in the generated ID. Any alphanumeric characters must be valid for a media ID. Use rules to create media IDs of many different formats. However, if the generated media ID is different from the label on the media, media management may be more difficult. The following is an example rule and the resulting generated media ID:

Barcode on the tape: 032945L1 Media ID rule: #N:2:3:4:5:6 Generated media ID: N32945

MEDIA_ID_PREFIX entry in vm.conf

If this entry is specified in vm.conf, it defines the media ID prefixes to use for media without bar codes. This entry is read and interpreted on the host where vmcheckxxx and vmupdate are running as part of the robot inventory operation.

MEDIA_ID_PREFIX = media id prefix

The best way to add media to a robot is to use the Robot Inventory Update Volume Configuration operation.

MM_SERVER_NAME entry in vm.conf

This entry specifies the name that other NetBackup servers and clients should use when they refer to this server.

MM_SERVER_NAME = host_name

See "Host name precedence in the vm.conf file" on page 114.

PREFERRED_GROUP entry in vm.conf

Veritas encourages the use of Veritas Product Authentication and Authorization for NetBackup Access Control (NBAC) instead of legacy security implementations.

For information about the PREFERRED_GROUP configuration entry, see the NetBackup 6.0 documentation. Information on Veritas Product Authentication and Authorization is available.

See the NetBackup Security and Encryption Guide:

http://www.veritas.com/docs/DOC5332

PREVENT_MEDIA_REMOVAL entry in vm.conf

This topic applies to the TL8 robots only.

Specifying this entry changes the default operation for TL8 robots. Without this entry present, NetBackup allows the removal of media.

If this entry is specified in vm.conf, TL8 robots run the SCSI command PREVENT MEDIUM REMOVAL. The robot's main door or the MAP cannot be opened while the robotic control daemon runs.

This entry is read and interpreted on the host on which the TL8 robot control daemon or process (tl8cd) runs.

To override **PREVENT MEDIA REMOVAL**, do one of the following:

- Use the test utility and run allow media removal.
- Use inject or eject for access, when volumes are added or moved.

RANDOM_PORTS entry in vm.conf

Use this entry to specify whether NetBackup chooses port numbers randomly or sequentially for communication with other NetBackup servers. This entry is read and interpreted on hosts on which vmd runs.

RANDOM PORTS = YES | NO

If YES or no entry exists (the default), NetBackup chooses port numbers randomly from those that are available in the allowed range.

If NO, NetBackup chooses numbers sequentially. NetBackup begins with the highest number in the allowed range, and then tries the next highest, and so on until a port is available.

On UNIX, if random ports are not specified in the NetBackup configuration, specify RANDOM_PORTS = NO in the vm.conf file.

See the NetBackup Administrator's Guide, Volume I:

http://www.veritas.com/docs/DOC5332

To specify no random ports in the NetBackup configuration file, do one of the following:

- Specify RANDOM_PORTS = NO in the bp.conf file on UNIX.
- Use the NetBackup Host Properties in the NetBackup Administration
 Console: NetBackup Management > Host Properties > Double-click on master server > Port Ranges > Use random port assignments.

REQUIRED_INTERFACE entry in vm.conf

This entry specifies the name of the network interface that the media server uses to connect to another media server.

REQUIRED INTERFACE = host name

A NetBackup server can have more than one network interface, and by default the operating system determines the one to use. To force NetBackup to connect through a specific network interface, use REQUIRED_INTERFACE and specify the name of that network interface.

See "Host name precedence in the vm.conf file" on page 114.

SERVER entry in vm.conf in NetBackup versions 8.0 and earlier

This entry determines the name other NetBackup servers should use when they refer to this server.

SERVER entries in the vm.conf file are used for NetBackup media server security.

SERVER = host name

SERVER entries work with the AUTHORIZATION_REQUIRED entry to control which hosts can monitor and control devices on this host.

If the <code>AUTHORIZATION_REQUIRED</code> entry exists, the <code>vm.conf</code> file must include a <code>SERVER</code> entry for every media server that controls devices on this host. If the <code>vm.conf</code> file contains any <code>SERVER</code> entries, it also must include a <code>SERVER</code> entry for itself or it cannot manage its own devices.

If no AUTHORIZATION_REQUIRED entry exists and no SERVER entries exist, any NetBackup server can monitor and control devices on this host.

For security, the entries that allow only specific hosts to access the devices must be added remotely.

This entry is read and interpreted on media servers on which the NetBackup $_{\mbox{vmd}}$ service runs.

Note: This entry is not applicable for NetBackup 8.1 or later versions.

SSO_DA_REREGISTER_INTERVAL entry in vm.conf

This entry determines the name other NetBackup servers should use when they refer to this server.

The following configuration entry applies to NetBackup servers:

SSO_DA_REREGISTER_INTERVAL = minutes

This vm.conf entry is for the Shared Storage Option (SSO) for Tape feature only. It is read and interpreted on the host on which ltid runs.

ltid on a scan host periodically registers its shared drives with EMM/DA to ensure that it is still provides the drive scanning function. Only one of the hosts that share a drive scan the drive. This reregistration allows conditions such as a device allocator restart to have minimal effect on use of shared drives.

The default for the reregistration interval is 5 minutes. Use the sso_DA_REREGISTER_INTERVAL entry to tune this interval. After the entry is added, stop and restart ltid for the change to take effect.

SSO_DA_RETRY_TIMEOUT entry in vm.conf

The following configuration entry applies to NetBackup servers:

SSO DA RETRY TIMEOUT = minutes

This vm.conf entry is for the Shared Storage Option (SSO) for Tape feature only. It is read and interpreted on the host on which ltid runs.

The Device Manager ltid delays before if one of the following events occurs:

- Problems during communications with EMM/DA.
- Failure trying to reserve a shared drive.

The default value for the delay is 3 minutes. Use the <code>sso_DA_RETRY_TIMEOUT</code> entry to tune this delay period. After the entry is added, stop and restart <code>ltid</code> for the change to take effect.

SSO_HOST_NAME entry in vm.conf

The following configuration entry applies to NetBackup servers:

SSO_HOST_NAME = host_name

This vm.conf entry is for the Shared Storage Option (SSO) for Tape feature only. It is read and interpreted on the host on which ltid runs.

This entry specifies the name that the current host uses to register, reserve, and release shared drives with EMM/DA. The default is the local host name.

TLH_mediatype entry in vm.conf

The following configuration entry applies to NetBackup servers:

TLH mediatype = Media Manager mediatype

If this entry is specified in vm.conf, IBM ATL media types in tape library Half-inch (TLH) robots are mapped to Media Manager media types. This entry is read and

interpreted on the host where vmcheckxxx and vmupdate are running as part of the robot inventory operation.

TLM_mediatype entry in vm.conf

The following configuration entry applies to NetBackup servers:

TLM mediatype = Media Manager mediatype

If this entry is specified in vm.conf, DAS/SDLC media types in tape library Multimedia (TLM) robots are mapped to Media Manager media types. This entry is read and interpreted on the host where vmcheckxxx and vmupdate are running as part of the robot inventory operation.

VERBOSE entry in vm.conf

If this entry is specified in vm.conf, all Media Manager components on the host are started with verbose logging enabled.

Use this option only if problems occur or if requested by Veritas support. After the problem is resolved, remove the debug logs or add a DAYS_TO_KEEP_LOGS entry.

Example vm.conf file

The following is an example of a vm.conf file, on host server1:

```
SERVER = server1
SERVER = server2
MEDIA_ID_PREFIX = NV
MEDIA_ID_PREFIX = NETB
ACS 3490E = HCART2
```

How to access media and devices on other hosts

For NetBackup to access media and device management functionality on a remote NetBackup host, you may need to add a <code>server</code> entry to the <code>vm.conf</code> file on the remote host.

The <code>SERVER</code> entries are used in the NetBackup <code>bp.conf</code> and <code>vm.conf</code> files for security. You can add the entries that allow only specific hosts to access those capabilities remotely.

If the vm.conf file on a remote host contains no SERVER entries, a host can manage media and devices on the remote host if it's added to the <code>bp.conf</code> file of the server you logged into. You do not need to add a SERVER entry to the <code>vm.conf</code> file.

If the vm.conf file on a remote host contains any SERVER entries, add a SERVER entry for the host on which the **NetBackup Administration Console** is running (the server you logged into) to that vm.conf file.

Assume that you have three hosts named eel, yak, and shark. You want to centralize device management on host shark and also permit each host to manage its own devices.

The following example scenario applies:

• The vm.conf file on shark contains the following:

```
SERVER = shark
```

The vm.conf file on shark does not require any additional SERVER entries, because all device management for shark is performed from shark.

 The vm.conf file on eel contains the following, which lets eel manage its own devices and permits shark to access them:

```
SERVER = eel
SERVER = shark
```

 The vm.conf file on yak contains the following, which lets yak manage its own devices and permits shark to access them:

```
SERVER = yak
SERVER = shark
```

Host name precedence in the vm.conf file

NetBackup identifies the media server by using the following name precedence:

- CLUSTER_NAME entry if present in vm.conf.
- MM SERVER NAME entry if present in vm.conf.
- REQUIRED_INTERFACE entry if present in vm.conf.
- The name of the host in the Server host properties of the master server.
- gethostname() name.

Chapter

6

Holds Management

This chapter includes the following topics:

- About Holds Management
- Creating a hold
- Viewing hold details
- Adding a backup image to an existing hold
- Releasing a hold

About Holds Management

NetBackup provides an option to put backup images on hold. The holds mechanism lets you retain the backup images for as long as you need without altering the expiration date.

You can manage the holds by using the command-line interface. You can perform the following:

- Create a hold.
 See "Creating a hold" on page 116.
- View the list of holds.
 See "Viewing hold details " on page 116.
- Add one or more backup images to an existing hold.
 See "Adding a backup image to an existing hold" on page 117.
- Release a hold from the backup image.
 See "Releasing a hold" on page 117.

Note: All hold operations except listing are audited.

Creating a hold

You can create a hold on one or more backup images by using the nbholdutil -create command.

Caution: Creating a hold on backup images may disrupt new backups from completing. Storage may fill up if previous backups are not automatically expired.

Note: When you retry a failed Hold creation, an empty hold is created if the backup images have expired between the initial hold and the retry.

To create a hold

The nbholdutil -create command lets you create a hold for a backup image.

On a command prompt on the NetBackup master server, enter nbholdutil -create with appropriate options and elements. For example:

```
nbholdutil.exe -create -holdname legal_case1 -backupid
win81.sky.com_1307425938 -allcopy
```

This command creates a hold called legal_case1. The backup image ID is win81.sky.com_1307425938. You must provide either the -allcopy option or the -primarycopy option. The -allcopy operation indicates that the hold includes all copies of the selected backup image. The -primarycopy option indicates that the hold includes only the primary copy of the selected backup image.

For more information about related command options, see the *Veritas NetBackup Commands Reference Guide*.

To display help information about the command and its options, enter nbholdutil -help [-option]

Viewing hold details

You can view the list of holds by using the nbholdutil -list command.

To view hold details

On a command prompt on the NetBackup master server, enter the nbholdutil -list command with appropriate options and elements. For example:

```
nbholdutil.exe -list
```

When you upgrade NetBackup to version 7.7, the legal holds are converted to user holds, which can be managed by using the nbholdutil command.

Note: In versions earlier than 7.7, OpsCenter allowed creating holds on backup images. Such holds are known as legal holds.

If the hold name of a legal hold is same as a user hold, all the hold names are renamed as follows:

- The legal hold names are suffixed with _1. For example, hold_1. The number 1 in the hold name denotes that it was a legal hold before conversion.
- The user hold names are suffixed with _3. For example, hold_3. The number 3 in the hold name denotes that it is a user hold.

For more information about related command options, see the *Veritas NetBackup Commands Reference Guide*.

To display help information about the command and its options, enter nbholdutil -help [-option]

Adding a backup image to an existing hold

You can add one or more backup images to an existing hold by using the nbholdutil -add command.

To add a backup image to an existing hold

On a command prompt on the NetBackup master server, enter the nbholdutil -add command with appropriate options and elements. For example:

```
nbholdutil.exe -add -holdname hold123 -reason "Reason1" -backupid
win81.sky.com_1307425938 -primarycopy
```

This command adds primary copy of the backup image win81.sky.com_1307425938 to the existing hold with hold ID equal to hold123.

For more information about related command options, see the *Veritas NetBackup Commands Reference Guide*.

To display help information about the command and its options, enter nbholdutil -help [-option]

Releasing a hold

You can release holds by using the nbholdutil -delete command.

Note: A backup image expires as per the expiry date when all the holds that include that backup image are released.

To release a hold

On a command prompt on the NetBackup master server, enter the nbholdutil -delete command with appropriate options and elements. For example:

nbholdutil.exe -delete -holdname legal_case1 -force -reason Legal Case1 resolved

This command releases a hold that is called legal_case1. For more information about related command options, see the *Veritas NetBackup Commands Reference Guide*

The command nbholdutil -delete lets you release a hold.

Chapter

Menu user interfaces on UNIX

This chapter includes the following topics:

- About menu user interfaces
- About the tpconfig device configuration utility
- About the NetBackup Disk Configuration Utility

About menu user interfaces

NetBackup provides several menu user interfaces on UNIX systems to help manage some NetBackup functionality:

- See "About the tpconfig device configuration utility" on page 120.
- See "About the NetBackup Disk Configuration Utility" on page 128.

These utilities are alternatives to using the **NetBackup Administration Console**. The terminology, general concepts, and results are the same regardless of the administration method that is used.

Note: Many NetBackup processes set an upper limit on the number of concurrently open file descriptors allowed by the process. That limit is inherited by the notify scripts run by the process. In the rare event that a command invoked by a notify script requires many additional file descriptors, the script must increase the limit appropriately before invoking the command.

About the tpconfig device configuration utility

UNIX systems only.

The NetBackup tpconfig device configuration utility is a character-based, menu-driven interface to configure robots, drives, and logon credentials. It can be used at any terminal (or terminal emulation window) for which termcap or terminfo is defined.

The NetBackup command utilities are alternatives to the **NetBackup Administration Console**. The terminology, general concepts, and results are the same regardless of which method you use.

After you configure devices, you can use the **NetBackup Administration Console** to configure volumes.

The following list describes the attributes of device configuration and how to use the tpconfig utility to configure those attributes.

The tpconfig device configuration utility attributes are as follows:

Robot number

You assign a robot number when you add a robot to the configuration. tpconfig prompts you to enter a number or accept the next available robot number that appears. This number identifies the robot in displays and listings, and it follows the robotic type in parentheses, such as TL8(2).

If you configure robots on multiple systems, robot numbers must be unique. If you connect drives from a robot to multiple systems, specify the same robot number for the robot on all systems.

Robotic control path

For most robots, you or the operating system creates this path in the /dev directory when you add a robot to the configuration. When the tpconfig utility prompts you, enter the path to the robotic control as found in the /dev directory. If the entries do not exist, more information is available.

See the *NetBackup Device Configuration Guide*, available at the following URL: http://www.veritas.com/docs/DOC5332

The control path to a robot may be on another host. If so, enter the host name of the host instead of a path. When you define a robot that another host controls by another host, the robot number must be the same on both hosts.

Information about how to configure robotic control is available.

See the *NetBackup Device Configuration Guide*, available at the following URL: http://www.veritas.com/docs/DOC5332

Host name

You must specify a host name in the following cases:

- When you add an ACS robot, enter the name of the host on which the ACS Library Software resides instead of a robotic control path.
- When you add a TLM robot, enter the DAS or Scalar DLC server name instead of a robotic control path.
- When you add one of the following robots that has robotic control on another host, you are prompted for the name of that host: TL8, TLD, or TLH robot.

No rewind on close device name

You specify an no rewind on close device name when you add a drive. Usually the letter n precedes or follows the device name. If the device name entries do not exist, you must create them.

See the *NetBackup Device Configuration Guide*, available at the following URL: http://www.veritas.com/docs/DOC5332

In $\tt tpconfig$ displays and $\tt tpconfig$ output, the device names are shown under the heading DrivePath.

Drive status

Drive status indicates whether NetBackup considers a drive available. You specify the initial drive status when you add a drive to the configuration. You can change the status. To do so, use the Update option of the Drive Configuration menu in tpconfig (ensure that the device daemonltid is not active). If the device daemon ltid is active, use the Administration Console Device Monitor or the vmoprcmd command.

About the tpconfig utility menu

The Device Configuration Utility menu contains the following information:

```
Device Management Configuration Utility
1) Drive Configuration
2) Robot Configuration
3) Credentials Configuration
4) Print Configuration
5) Help
6) Quit
Enter option:
```

Table 4-1 describes the main menu selections.

Menu choice	Description
Drive Configuration	Opens a menu to add, delete, or update drive definitions; list definitions of drives and robots; or configure drive paths.
Robot Configuration	Opens a menu to add, delete, or update robot definitions or list definitions of drives and robots
Credentials Configuration	Opens a menu to add, delete, update, or list credentials for the following: NDMP filer Disk array OpenStorage server Virtual machine
Print Configuration	The List Configuration commands on subsequent menus let you display the current configuration on the screen or write it to a file. If you specify the -d option only on the tpconfig command, tpconfig writes the current configuration to stdout (the screen) without invoking the menus. Other command options are available. Run tpconfig -help. See the <i>NetBackup Commands Reference Guide</i> , available at the following URL: http://www.veritas.com/docs/DOC5332
Help	Online Help is available on the main menu and most submenus.
Quit	Terminates the utility and returns you to the UNIX prompt.

 Table 4-1
 tpconfig main menu selections

You can return to the main menu from anywhere in the utility by entering **Ctrl C** or by using the **Escape** key.

Starting the tpconfig device configuration utility

Several methods exist to start the tpconfig utility.

Note: If the Media Manager device daemon is running, stop it by using the stopltid command.

To start tpconfig from a UNIX shell

 Enter the following command in a UNIX shell (you must have root user privileges):

/usr/openv/volmgr/bin/tpconfig

Adding robots

When you configure robots and drives, first add the robots by using the **Robot Configuration** menu. Then add the drives by using the **Drive Configuration** menu.

To change standalone drives to robotic, use the **Update** option of the **Drive Configuration** menu.

See "Updating a drive configuration" on page 125.

To add a robot

- 1 Select the Robot Configuration menu.
- 2 Select the Add option.
- 3 From the list of possible robot types, select the one you want to add.
- 4 Enter a robot number that you know is unused or accept the default robot number.
- 5 Indicate where the robotic control for the library is by entering the device file path or library name. The **Help** option on the **Robot Configuration** menu has examples of typical path names.
- If robotic control is on another host, enter that host name.
 For an ACS robot, enter the name of the ACS library software host. For a TLM robot, enter the name of the DAS or Scalar DLC server.
 - If robotic control is on this host, enter the device file path or library name. The Help option on the Robot Configuration menu has examples of typical path names.

For an ACS robot, enter the name of the ACS library software host. For a TLH robot on an AIX system, enter the LMCP Device File; otherwise, enter the Automated Tape Library Name.

For a TLM robot, enter the name of the DAS or Scalar DLC server.

7 If no conflicts are detected with the new configuration, a message appears to indicate that the robot was added.

Adding drives

Use the following procedure to add a drive.

To add a drive

- 1 Select the Drive Configuration menu.
- 2 Select the Add option.
- **3** From the list of possible drive types, select the one you want to add.
- 4 Enter the no rewind on close device path as shown in the /dev directory.

The **Help** option on the **Drive Configuration** menu has examples of typical path names.

- 5 Enter the drive status (Up or Down).
- 6 If a robot exists to which you can add the drive, specify whether to add the drive to the robot. Alternatively, you can configure the drives as a standalone drive.

If there are no robots to which you can add the drive, tpconfig automatically adds the drive as a standalone drive.

If you add a drive to a robot and more than one possible robot exists, enter the number of the robot that controls the drive.

Depending on the type of robot, you may also be prompted to add the robot drive number.

7 For a drive in an ACS robot, you are prompted for four drive identifiers.

More information on ACS robots is available.

See the NetBackup Device Configuration Guide, available at the following URL:

http://www.veritas.com/docs/DOC5332

For a drive in a TLH robot, you are prompted for an IBM device number.

For a drive in a TLM robot, you are prompted for a DAS or Scalar DLC drive name.

More information is available.

See the NetBackup Device Configuration Guide, available at the following URL:

http://www.veritas.com/docs/DOC5332

8 Type a drive name or press the **Enter** key to use the default drive name.

If you use the shared drives option, all hosts that share the same physical drive must use the same name for the drive. Descriptive drive names are recommended.

Updating a robot configuration

Use the following procedure to change the robot number or the robotic control path.

To change the robot number or the robotic control path

1 On the main menu, select **Robot Configuration**.

If only one robot is configured, you do not have to select **Update** or enter the robot number. If only one robot is configured, skip to step 4.

- 2 On the Robot Configuration menu, choose Update.
- **3** Enter the number of the robotic library you want to change.
- 4 Enter a new robot number to replace the existing robot number or press **Enter** to retain the current robot number.

You are prompted to enter robotic control information. The actual prompts depend on the type of robotic library you update.

5 Enter the appropriate robotic control path or name of the server that hosts the robot.

Updating a drive configuration

You can change information for a drive (for example, you can add it to a robot).

To change information for a drive

- 1 On the main menu, select **Drive Configuration**.
- 2 On the Drive Configuration menu, choose Update.
- **3** Enter the name of the drive you want to update.

The current drive information is displayed, followed by prompts to change each field.

4 Enter a new value or press **Enter** to retain the existing value.

One of the prompts asks if you want to configure the drive in a robot. If you do, tpconfig adds the drive immediately or gives you the opportunity to choose from any existing robot of the appropriate type.

When you have responded to all prompts, a revised Drive Information display appears, along with the following prompt:

Are you sure you want to UPDATE drive name xxxxx? (y/n) n:

5 Answer yes by pressing y.

Deleting a robot

Use the following procedure to delete a robot.

To delete a robot

1 On the main menu, select **Robot Configuration**.

If only one robot is configured, you do not have to select **Update** or enter the robot number. If only one robot is configured, skip to step 4.

- 2 On the Robot Configuration menu, choose Delete.
- 3 If more than one robot is configured, enter the number of the robot to delete.
- 4 Enter y to delete the robot.

If you respond with ${\bf n},$ press any key to return to the ${\bf Drive \ Configuration}$ menu.

Deleting a drive

Use the following procedure to delete a drive.

To delete a drive

- 1 On the main menu, select Drive Configuration.
- 2 In the Drive Configuration menu, select Delete.
- **3** Enter the name of the drive you want to delete:
- 4 Enter y to delete the drive.

If you respond with ${\bf n},$ press any key to return to the ${\bf Drive \ Configuration}$ menu.

Configuring drive paths

Use the following procedures to configure and manage drive paths.

To display the drive path menu

- 1 From the Drive Configuration menu, select Drive Path Configuration.
- 2 Enter a drive name.

To add a drive path

- 1 Select Add from the Drive Path Configuration menu.
- 2 Enter a valid drive path.
- **3** Specify the drive status on the path.

The drive can be Up, Down, or Disabled for the path.

To delete a drive path

- 1 Select **Delete** from the **Drive Path Configuration** menu.
- 2 Enter the drive path to delete.

To update a drive path

- 1 Select Update from the Drive Path Configuration menu.
- 2 Enter the drive path to update.
- 3 Specify a new drive path or press **Enter** to update the status of the drive path.
- **4** A prompt similar to the following is displayed:
- 5 Enter the path status.

Configuring host credentials

You can add, delete, update, or configure the following default host credentials:

NDMP filer

You can add the credentials for a specific filer on a specific server. You also can add credentials to be used for all NDMP Filers by all NetBackup servers.

- Disk array SharedDisk is supported on NetBackup 6.5 media servers only.
- OpenStorage server
- Virtual machine

To configure host credentials

- 1 On the main menu, select **Credentials Configuration**.
- 2 On the credentials menu, select the type of credential you want to configure.

Please select the type of host you are trying to configure:
 1) (N)dmp Filer
 2) (D)isk Array Management Server
 3) (O)penStorage Server
 4) (V)irtual Machine

3 Select an option at the specific credentials menu and follow the prompts.

Displaying and writing the device configuration

You can display or write out the current configuration from every menu in ${\tt tpconfig}.$

To display the configuration from the main menu

- 1 Press 4) Print Configuration.
- 2 Press Enter.

To display the configuration from a submenu

Select the List Configuration option by pressing the corresponding number.

To write the current configuration to a file

- 1 On the main menu, press 4) Print Configuration.
- 2 Enter the file name.

To write the current configuration to standard output

• Enter the following command in a UNIX shell:

tpconfig -d

About the NetBackup Disk Configuration Utility

The NetBackup Disk Configuration Utility is a character-based, menu-driven interface that lets you configure and manage disk storage entities. Use this utility for optional NetBackup products that use disk pool storage. It can be used at any terminal (or terminal emulation window) for which termcap or terminfo is defined.

The NetBackup command utilities are alternatives to the **NetBackup Administration Console**. The terminology, general concepts, and results are the same regardless of which method you use.

After you configure the disk storage, you also can configure a disk storage unit by using a UNIX utility.

Managing OpenStorage servers and disk pools

Use the OpenStorage Disk Management menu to configure and manage disk storage for the OpenStorage Disk Storage Unit Option.

To manage OpenStorage servers and disk pools

1 From the NetBackup disk configuration utility main menu, press **o** (OpenStorage Disk Management) to display the OpenStorage Disk Management menu.

The menu contains the following information:

OpenStorage Disk Management

- a) Add Storage Server
- u) Update Storage Server
- r) Remove Storage Server
- v) View Storage Server
- g) Get Storage Server Configuration
- e) Engage Storage Server Configuration
- p) Preview Disk Volumes
- n) Create New Disk Pool
- t) Take Disk Pool Inventory
- m) Merge Two Disk Pools
- c) Change Disk Pool
- s) Change Disk Pool State
- w) Update Disk Pool Replication Properties From Storage Server
- k) Add Volumes To Disk Pool
- d) Delete Disk Pool
- 1) List Disk Pools
- h) Help
- q) Quit Menu

ENTER CHOICE:

 Select a menu option and follow the prompts to configure and manage OpenStorage.

Managing global disk attributes

Use the Global Disk Management Attributes menu to configure and manage disk storage attributes for all disk pool features.

To manage global disk attributes

1 From the NetBackup disk configuration utility main menu, press **g** (Global Disk Management Attributes) to display the Global Disk Management Attributes menu.

The menu contains the following information:

2 Select a menu option and follow the prompts to configure and manage attributes.

Chapter

Reference topics

This chapter includes the following topics:

- Host name rules
- About reading backup images with nbtar or tar32.exe
- Factors that affect backup time
- Methods for determining the NetBackup transfer rate
- NetBackup notify scripts
- Media and device management best practices
- About TapeAlert
- About tape drive cleaning
- How NetBackup selects drives
- How NetBackup reserves drives
- How NetBackup selects media
- Volume pool and volume group examples
- Media formats
- Media and device management processes
- About Tape I/O commands on UNIX

Host name rules

NetBackup uses host names to identify, communicate with, and initiate processes on NetBackup client and server computers. The correct use of host names during configuration is essential to the proper operation of NetBackup.

See "About dynamic host name and IP addressing" on page 57.

On Windows:

NetBackup uses TCP/IP host names to connect to NetBackup servers and clients. NetBackup validates its connections by performing a reverse host name lookup. That is, NetBackup determines the IP address of a connection and then uses the IP address to look up the host name with gethostbyaddr(). The host name and address resolution must be set up correctly in DNS, WINS, or the local %Systemroot%\system32\drivers\etc\hosts file (if necessary).

Note: Place the system host name and IP address in the %Systemroot%\system32\drivers\etc\hosts file to accelerate name lookups.

How NetBackup uses host names

A major consideration is the extent to which you qualify host names. In many cases, the short host name of a computer is adequate. If the network environment contains multiple domains, qualify host names to the extent that servers and clients can identify each other in a multi-domain environment.

For example, use a name such as mercury.bdev.null.com or mercury.bdev rather than only mercury.

The following topics discuss how NetBackup stores and uses host names. These topics also address factors to consider when you choose host names.

Note: (On Windows) Veritas recommends that you do not change the host name of a NetBackup server. You may need to import all previously used media to the server before you can use it under the new host name.

The following table discusses the topics that address how NetBackup stores and uses host names.

Торіс	Description
Server and client names on UNIX servers and clients	On both UNIX servers and clients, the SERVER entries in the bp.conf file define the NetBackup servers that are allowed access. The first SERVER entry identifies the master server. The first SERVER entry indicates the server to which client requests are made. For this reason, the SERVER name must be one by which all clients can connect to the server.
	If more than one SERVER entry exists, the additional entries identify other NetBackup servers that can initiate scheduled backups on the client. The <code>bp.conf</code> file must have multiple SERVER entries if you configure remote media servers. The NetBackup Request daemon (<code>bprd</code>) and NetBackup Database Manager daemon (<code>bpdbm</code>) do not run on any server other than a master.
	When a client makes a list or restore request to the server, the NetBackup client name is used to determine whether to allow the operation. (The client name as specified on the client.) The client name that is used is usually the $CLIENT_NAME$ from the bp.conf file of the client. Or, the client name can be the actual host name of the client if not in the bp.conf file. Alternate client restores can use the name that is specified through the user interface or with a parameter on the bprestore command.
	For a successful request, the client name must match the name that is specified for the client in the NetBackup configuration on the server. The only exception to this rule is if the server is configured to allow alternate client restores.
Host names on Windows servers and PC clients	Windows NetBackup servers and clients also have SERVER and CLIENT_NAME settings. On these systems, specify server and client settings in the NetBackup Administration Console.
Policy configuration	(On Windows) The configured name for a client is the host name as it's added to a policy. This name is how the client is identified in the NetBackup configuration.
	(On UNIX) The configured name for a client is the host name as it's added to a policy. This name is how the client is identified in the NetBackup configuration. NetBackup also adds a CLIENT_NAME entry to a UNIX client's bp.conf file when software is first installed on the client.
	The server uses the client's configured name to connect to the client and start the processes that satisfy client requests. Always use qualified host names to add clients to a policy so that all NetBackup servers can connect to the clients.
	When a client makes a user backup, archive, or restore request to the NetBackup server, the server uses the peer name of the client. The peer name (identified from its TCP connection) is used to determine the client's configured name.
	If you add a client to more than one policy, always use the same name in all cases. If the same name is not used, the client cannot view all the files that are backed up on its behalf. In this case, file restores become complicated because both user action and administrator action is required to restore from some of the backups.

Table 5-1 How NetBackup stores and uses host names

Tabl	How NetBackup stores and uses host names (continued)
Торіс	Description
Image catalog	A subdirectory in the image catalog is created for a client when a backup is first created for that client. The subdirectory's name is the client's configured name.
	Every backup for a client has a separate file in this subdirectory. Each of these backup records contains the host name of the server on which the backup was written.
Error catalog	NetBackup uses the entries in the error catalog for generating reports. These entries contain the host name of the server that generates the entry and the client's configured name, if applicable. The server host name is normally the server's short host name. (For example, <i>servername</i> instead of <i>servername.null.com</i> .)
Catalog backup information	If you include a media server's catalog files in the NetBackup catalog, qualify the host name of the media server in the file path. Qualified names are necessary because they allow the master server to connect to the media server.
	y NetBackup user-defined strings must not contain non-US ASCII characters, uding the following:
	Host name (master server, media server, Enterprise Media Manager (EMM) server, volume database host, media host, client)
• F	Policy name
• F	Policy keyword (Windows only)
• E	Backup, Archive, and Restore keyword (Windows only)
∎ S	Storage unit name
∎ S	Storage unit disk pathname (Windows only)
∎ F	Robot name
• [Device name
∎ S	Schedule name
■ N	Media ID

- - -
- Volume group name
- Volume pool name
- Media description
- Vault policy names
- Vault report names
- BMR Shared Resource Tree (SRT) name

nbcertcmd command

change

Updating NetBackup after changing the host name

Do not change the host name of a NetBackup server. A name change might require that all previously used media be imported to the server before the host can be used under the new name.

Use the following steps to update the NetBackup configuration if a client's host name is changed.

To update NetBackup after a master	See "To update NetBackup after a master server
server name change	name change" on page 135.
To update NetBackup after a client name	See "To update NetBackup after a client name

change" on page 136.

To update NetBackup after a master server name change

- 1 On the master server, delete the client's old name from all policies where it exists and add the client's new name to those policies. You do not need to reinstall NetBackup software on the client. The client continues to have access to all previous backups.
- 2 (On UNIX) Create a symbolic link from the client's old image directory to its new image directory. For example,

```
cd /usr/openv/netbackup/db/images ln -s
old client name new client name
```

3 (On Windows) Create a file named ALTPATH in the image catalog directory.

For example, if the client name is client1, the ALTPATH file is created in the following location:

```
Install_path\VERITAS\NetBackup\db\images\client1\
ALTPATH
```

4 (On Windows) Create a directory for the new client2 in the \images directory:

Install_path\VERITAS\NetBackup\db\images\client2

5 (On Windows) On the first line of the client1\ALTPATH file, specify the path to the directory for the new client. The path is the only entry in the ALTPATH file.

Install_path\VERITAS\NetBackup\db\images\client2

To update NetBackup after a client name change

1 On PC clients, change the client name setting either through the user interface or in a configuration file.

See the online Help in the Backup, Archive, and Restore client interface.

2 On UNIX clients, change the CLIENT_NAME value in the bp.conf file to the new name.

If users on UNIX clients have a bp.conf file in the \$HOME directory, users must change CLIENT NAME in that file to the new name.

Special considerations for Domain Name Service (DNS)

In some requests to the master server, client software sends the name that it obtains through its gethostname library function (on Windows) or the gethostname(2) library function (on UNIX). If the name is unknown to the master server Domain Name Service, the master server may not be able to reply to client requests.

This possible situation depends on how the client and the server are configured. If gethostname on the client (on Windows) or gethostname (2) on the client (on UNIX) returns the host names that DNS on the master server cannot resolve, problems occur.

One possible solution is to reconfigure the client or the master server DNS hosts file. Another option is to create a special file in the altnames directory on the master server. The file forces the translation of NetBackup client host names.

On Windows:

install_path\NetBackup\db\altnames\host.xlate

On UNIX:

/usr/openv/netbackup/db/altnames/host.xlate

Each line in the host.xlate file contains three elements: a numeric key and two host names. Each line is left-justified, and a space character separates each element of the line:

key hostname_from_ client client_as_known_by_server

Where

 key is a numeric value used by NetBackup to specify the cases where translation is to be done. Currently this value must always be 0, which indicates a configured name translation.

- hostname_from_client is the value to translate. The client name must correspond to the name that is obtained by running the client's gethostname (on Windows) or gethostname(2) (on UNIX). The value must be sent to the server in the request.
- client_as_known_by_server is the name to substitute for hostname_from_client for request responses. The name must match the name in the NetBackup configuration on the master server and must also be known to the master server's network services.

Consider the following example:

0 xxxx xxxx.eng.aaa.com

The line specifies that when the master server receives a request for a configured client name (numeric key 0), the name xxxx.eng.aaa.com always replaces xxxx.

The substitution resolves the problem if the following conditions are true:

- When gethostname (on Windows) or gethostname(2) (on UNIX) is run on the client, it returns xxxx.
- The master server's network services gethostbyname library function (on Windows) or gethostbyname (2) library function (on UNIX) did not recognize the name xxxx.
- The client was configured and named in the NetBackup configuration as xxxx.eng.aaa.com. And, this name is also known to network services on the master server.

About reading backup images with nbtar or tar32.exe

NetBackup uses tar-formatted backup images. By using the NetBackup tar32.exe on Windows or nbtar on UNIX or Linux, NetBackup can understand compressed files, sparse files, long pathnames, and ACL information. It offers features similar to those in cpio.

Although non-NetBackup restore utilities that process tar-formatted images can be used to restore files, they provide only limited restore capabilities. You cannot use the NetBackup tar32.exe or nbtar to extract files from a NetBackup for Windows backup image.

Consequences of using non-NetBackup restore utilities

Non-NetBackup restore utilities do not supply all of the restore capabilities that the NetBackup /usr/openv/netbackup/bin/nbtar provides. Possible problems result.

The following is a list of consequences that can occur if using non-NetBackup restore utilities:

- Compressed backups cannot be recovered.
- Multiplexed backups cannot be recovered.
- Solaris extended attributes cannot be restored to a client.
- VxFS named data streams cannot be restored to a client.
- Raw partitions cannot be recovered. (This applies to FlashBackup images as well.)
- NDMP client backup images cannot be restored, though NDMP vendors may have tools or the utilities that can perform a restore directly from the media.
- Non-NetBackup versions of restore utilities may have trouble with sparse files and often skip sparse files.
- HP CDFs are restored with non-NetBackup versions of restore utilities. The directory is no longer hidden and the name of the directory has a + appended to it.
- If the backup spans more than one piece of media, you must read and combine the fragments from the media to give to the restore utility. To combine the fragments, the system's dd command may be useful.

Another possibility is to use a restore utility on the fragments. To use a restore utility on fragments can allow recovery of any file in the backup other than the one that spanned the media.

Some versions of the HP9000-800 $/{\tt bin/tar}$ command are known to give a directory checksum error for the second fragment of a backup that crossed media.

• Some versions of Solaris tar combine the atime, mtime, and ctime strings with the file name and create the file paths that are not desirable.

Restoring files with non-NetBackup restore utilities (on UNIX)

This sequence assumes that the media is known to Media Manager and that the tape drive is under Media Manager control.

Before you begin, obtain the following information:

- The media ID of the tape that contains the required backup.
- The tape file number of the backup on the tape.
 See the NetBackup Images on Media report for this tape.
- The tape type and density.

The tape pool.

To restore files with a non-NetBackup utility

1 Enter the following command:

```
tpreq -m media_id -a r -d density -p poolname -f
/tmp/tape
```

Where the following is true:

media_id is the media ID of tape that contains the backup.

density is the density of the tape.

poolname is the volume pool to which the tape belongs

- 2 Enter the following command: mt -f /tmp/tape rew
- 3 Enter the following command: mt -f /tmp/tape fsf file_#

Where the following is true:

file_# is the tape file number of the backup on tape. Determine the tape file number by checking the NetBackup Images on Media report for the tape.

- 4 Enter the following command: mt -f /tmp/tape fsr
- 5 Enter the following command:

/bin/nbtar -tvfb /tmp/tape blocksize

Where the following is true:

blocksize is 64 (assume that the tape is written with 32K blocks)

6 Enter the following command: tpunmount /tmp/tape

Considerations for file restoration with non-NetBackup restore utilities (on UNIX)

When you restore files with non-NetBackup restore utilities, be aware of the following considerations:

- The file restoration procedure with non-NetBackup utilities does not apply to the encrypted backups that use NetBackup Encryption. Encrypted backups are recoverable. However, the backups cannot be decrypted.
- To determine if a backup is encrypted, run a non-NetBackup restore utility such as tar -t before the recovery. The output for an encrypted backup is similar to the following example:

erw-r--r- root/other Nov 14 15:59 2014 .EnCryYpTiOn.388 -rw-r--r- root/other Oct 30 11:14 2015 /etc/group.10-30

Where the $_{e}$ at the beginning of line one indicates that the backup is encrypted. (Additional messages appear during recovery.)

 The file restoration procedure with non-NetBackup utilities does not work on the Solaris platform. You cannot use /usr/sbin/tar on Solaris to read NetBackup backups. The Solaris tar command uses the ctime and the atime fields differently than other tar commands.

When /usr/sbin/tar is used to restore backups, directories with large numbers are created at the top level. These directories are from the ctime and the atime fields being read as pathnames.

You can use /usr/openv/netbackup/bin/nbtar to read the backups on Solaris platforms.

 Steps 1 and 6 from the file restoration procedure with non-NetBackup utilities are optional in a standalone environment. If step 1 is skipped, DOWN the drive and then substitute the /dev path of the drive in place of /tmp/tape in the other steps. Remember to UP the drive when you are done.

See "To restore files with a non-NetBackup utility" on page 139.

About the files that restores generate

The <code>nbtar</code> command and any restore utility that processes tar-formatted images, can generate a number of files depending on the circumstances of the recovery, as Table 5-2 shows.

File	Description
@@MaNgLeD.nnnn	For backups containing pathnames longer than 100 characters, nbtar generates the files that are named @@MaNgLeD.nnnn that contain the actual file.
@@MaNgLeD.nnnn_Rename	nbtar generates another file (@@MaNgLeD.nnnn_Rename) that explains how to rename the @@MaNgLeD.nnnn files to return the files to the correct location.
@@MaNgLeD.nnnn_Symlink	For long names of symbolic links, nbtar generates the files that are named @@MaNgLeD.nnnn_Symlink. These files contain descriptions of the symbolic links that must be made to return a link to the correct file.

Table 5-2	Files that restores generate
-----------	------------------------------

Table 5-2 Files that restores generate (continued)		
File	Description	
For cross-platform VxFS extent attribute restores, nbtar creates and stores extent attributes in .ExTeNt.nnnn files in the root directory	The files can either be deleted or read and the extent attributes regenerated by hand to the corresponding files.	

Factors that affect backup time

The amount of time that NetBackup requires to complete a backup is an important factor in setting up schedules. The importance of time is particularly true for the sites that handle large amounts of data. For example, the total backup time can exceed the time that is allotted to complete backups and interfere with normal network operations. Longer backup times also increase the possibility of a problem that disrupts the backup. The time to back up files can also give an indication of how long it may take to recover the files.

Figure 5-1 shows the major factors that affect backup time.

Figure 5-1	Backup time formu	Backup time formula		
Backup time	= Total data + Transfer rate	Compression factor (optional)	x	Device delays

Total amount of data to back up

The total amount of data to back up depends on the size of the files for each client in the policy. The total amount of data also depends on whether the backup is a full backup or an incremental backup.

The implications are as follows:

- Full backups involve all the data. Therefore, a full backup usually takes longer than an incremental backup.
- Differential incremental backups include only the data that changed since the last full or incremental backup.
- Cumulative incremental backups include all the data that changed since the last full backup.

For incremental backups, the amount of data depends on the frequency with which files change. If a large number of files change frequently, incremental backups are larger.

Transfer rate

The transfer rate depends on the following factors.

Table 5-3 Transfer rate factors		
Factor	Description	
Speed of the backup device	Backups that are sent to tapes with a transfer rate of 800 kilobytes per second are generally faster than tapes with a transfer rate of 400 kilobytes. (Assume that other factors allow for the faster transfer rate.)	
Available network bandwidth	The available bandwidth is less than the theoretical network bandwidth and depends on how much other network traffic is present. For example, multiple backups occurring on the same network compete for bandwidth.	
Speed with which the client can process the data	The speed varies with the hardware platform and depends on the other applications that run on the platform. File size is also an important factor. Clients can process larger files faster than smaller ones. A backup for 20 files, 1 megabyte each, is faster than a backup for 20,000 files that are 1 kilobyte each.	
Speed with which the server can process the data	Like client speed, server speed also varies with the hardware platform and depends on the other applications that run on the platform. The number of concurrent backups being performed also affects server speed.	
Network configuration can affect performance	For example, when some computers run full-duplex and some run half-duplex in an Ethernet environment, the throughput is significantly reduced.	
Compression (on UNIX)	Software compression often multiplies the backup time by a factor of two or three for a given set of data.	
Device delays	Device delays can be due to the following factors:	
	The device may be busy or slow to load the media.The device may be slow to find the location on the media at which to start writing the backup.	
	These delays can vary widely and depend on the devices and the computing environments.	

Methods for determining the NetBackup transfer rate

Calculate three variations of the backup transfer rate by using NetBackup report data.

Three NetBackup transfer rates and calculation methods are available.

Transfer rate	Description
Network transfer rate	The network transfer rate is the rate provided in the All Log Entries report.
	The network transfer rate considers only the time it takes to transfer data over the network from client to server.
	This rate ignores the following:
	 The time the device requires to load and to position media before a backup.
	 The time that the tape file requires to close and write an additional NetBackup information record to the tape.
Network transfer plus end-of-backup processing rate	This rate ignores the time it takes to load and to position media before a backup. However, the rate does include the end-of-backup processing that is ignored in the network transfer rate. To determine this rate, use the All Log Entries report and calculate the time from the message:
	begin writing backup id xxx
	until the message
	successfully wrote backup id xxx
	To calculate the transfer rate, divide this time (in seconds) into the total bytes that are transferred. (The total bytes that are transferred are recorded in the All Log Entries report.)
Total transfer rate	This transfer rate includes the time it takes to load and position the media as well as the end-of-backup processing. Use the List Client Backups report to calculate the transfer rate by dividing Kilobytes by Elapsed Time (converted to seconds).

 Table 5-4
 NetBackup transfer rates

On Windows, the Microsoft Windows System Monitor also displays the NetBackup transfer rate.

Examples of the reports that provide backup data to calculate transfer rates

Assume that the reports provide the following data.

Sample All Log Entries report:

```
TIME SERVER/CLIENT TEXT
04/28/09 23:10:37 windows giskard begin writing backup
id giskard_0767592458, fragment 1 to
media id TL8033 on device 1 . . .
04/29/09 00:35:07 windows giskard successfully wrote
backup id giskard_0767592458,
fragment 1, 1161824 Kbytes at
230.325 Kbytes/sec
```

Sample List Client Backups Report:

Client:	giskard
Backup ID:	giskard_0767592458
Policy:	production_servers
Client Type:	Standard
Sched Label:	testing_add_files
Schedule Type:	Full
Backup Retention Level:	one week (0)
Backup Time:	04/28/09 23:07:38
Elapsed Time:	001:27:32
Expiration Time:	05/05/09 23:07:38
Compressed:	no
Kilobytes:	1161824
Number of Files:	78210

The following three rates were compiled with the backup data from the sample reports:

Network transfer rate:

1161824 KB at 230.325 KB per second

Network transfer plus end-of-backup processing rate:

23:10:30 - 00:35:07 = 01:24:30 = 5070 seconds

1161824 KB/5070 = 229.157 KB per second

Total transfer rate:

Elapsed time = 01:27:32 = 5252 seconds

1161824 Kbytes/5252 = 221.216 KB per second

NetBackup notify scripts

NetBackup provides scripts or batch files that can collect information and be used to notify administrators of specific events.

Many of the scripts are located in the goodies directory, which contains sample shell scripts to modify. The scripts in the goodies directory are not supported but are intended as examples to customize.

The goodies directory is found in the following location:

On Windows: Install_path\NetBackup\bin\goodies\

On UNIX: /usr/openv/netbackup/bin/goodies

Notes about using scripts

- Ensure that others can run the script after modifying. To do so, run chmod ugo+rx script name, where script name is the name of the script.
- If you use either the bpstart_notify or bpend_notify scripts, do not include any commands that write to stdout. NetBackup sends the output that is written to stdout to the server as part of the backup. The resulting backup can abort with an error message that pertains to block sizes.
 Also, ensure that all commands in the scripts are appropriate to the client platform. For example, the -s parameter is invalid for the UNIX mail command on some UNIX platforms. Its use can cause data to be written to stdout or stderr.
- Many NetBackup processes set a limit on the number of concurrently open file descriptors that are allowed. That limit is inherited by the notify scripts run by the process. In the rare event that a command invoked by a notify script requires many additional file descriptors, the script must increase the limit appropriately before invoking the command.

The following topics describe the scripts that are active on the master server and those that are active on the client.

To use the client scripts, first create the script on the client.

Additional comments appear in the scripts.

backup_notify script

The <code>backup_notify.cmd</code> script (on Windows) and the <code>backup_notify</code> script (on UNIX) runs on the NetBackup server where the storage unit is located. It's called each time a backup is successfully written to media.

The scripts are located in the following directories:

On Windows: Install path\NetBackup\bin\backup notify.cmd

On UNIX: /usr/openv/netbackup/bin/backup_notify

NetBackup passes the following parameters to this script:

- The name of the program performing the backup
- The backup-image name or path

See the following Windows example:

backup notify.cmd bptm host 0695316589

backup_exit_notify script

The backup_exit_notify.cmd script (on Windows) and the backup_exit_notify script (on UNIX) run on the master server. It's called to perform site-specific processing when an individual backup completes.

The scripts are located in the following directories:

On Windows: *Install_path*\NetBackup\bin\backup_exit_notify.cmd

On UNIX: /usr/openv/netbackup/bin/backup_exit_notify

clientname	Specifies the name of the client from the NetBackup catalog.
policyname	Specifies the policy name from the NetBackup catalog.
schedname	Specifies the schedule name from the NetBackup catalog.
schedtype	Specifies one of the following: FULL, INCR (differential incremental), CINC (cumulative incremental), UBAK, UARC
exitstatus	Specifies the exit code for the entire backup job.
stream	Specifies the backup stream number for a job.
	0 = The backup job is not running multiple data streams.
	-1 = The job is a parent job.

done trying Specifies whether the job will retry.

0 = The job is not complete and will retry.

1= The job is complete and will not retry.

If the system is configured to make 3 attempts in 12 hours, the job could run this script up to 3 times. On the final attempt, the done_trying flag is set to 1. The job has either completed successfully or has failed and exhausted the number of tries.

See the following UNIX example:

```
backup_exit_notify clientname1 pol_prod sched_fulls FULL 0 -1 1
backup_exit_notify clientname2 pol_prod sched_incr INCR 73 0 1
```

bpstart_notify script (UNIX clients)

On UNIX clients, NetBackup calls the <code>bpstart_notify</code> script each time the client starts a backup or an archive.

Note: Ensure that others can run this script on the client before it's used. To do so, run chmod ugo+rx script_name, where script_name is the name of the script.

To use this script, copy the following file from the server:

/usr/openv/netbackup/bin/goodies/bpstart_notify

Then place the script in the following location on the UNIX client:

/usr/openv/netbackup/bin/

Modify the script and ensure that you have permission to run the script.

The <code>bpstart_notify</code> script runs each time a backup or an archive starts and initialization is completed. The script runs before the tape is positioned. This script must exit with a status of 0 for the calling program to continue and for the backup or archive to proceed. A nonzero status causes the client backup or archive to exit with a status of <code>bpstart_notify_failed</code>.

If the /usr/openv/netbackup/bin/bpstart_notify script exists, it runs in the foreground. The bpbkar process on the client waits for the script to complete before it continues. Any commands in the script that do not end with an ampersand character (&) run serially.

The server expects the client to respond with a continue message within the time that the BPSTART TIMEOUT option specifies on the server. The default for

BPSTART_TIMEOUT is 300 seconds. If the script needs more time than 300 seconds, increase the value to allow more time. (The BPSTART_TIMEOUT option corresponds to the **Backup start notify timeout** on the **Timeouts** host properties.)

Note: The Client read timeout (CLIENT_READ_TIMEOUT option) must be equal to or greater than the Backup start notify timeout (BPSTART_TIMEOUT option). If the Client read timeout is less than the Backup start notify timeout, the job can time out while the bpstart_notify script is running.

NetBackup passes the following parameters to the script:

clientname	Specifies the name of the client from the NetBackup catalog.
policyname	Specifies the policy name from the NetBackup catalog.
schedname	Specifies the schedule name from the NetBackup catalog.
schedtype	Specifies one of the following: FULL, INCR (differential incremental), CINC (cumulative incremental), UBAK, UARC

Note: The <code>bpstart_notify</code> script also runs for NetBackup catalog backups if a .policyname[.schedule] is not specified.

For example:

```
bpstart_notify client1 pol_cd4000s sched_fulls FULL
bpstart_notify client2 pol_cd4000s sched_incrementals INCR
bpstart_notify client3 pol_cd4000s sched_fulls FULL
bpstart_notify client4 pol_cd4000s sched_user_backups UBAK
bpstart_notify client5 pol_cd4000s sched_user_archive UARC
```

To create a <code>bpstart_notify</code> script for a specific policy or policy and schedule combination, create script files with a *.policyname* or *.policyname.schedulename* suffix. The following are two examples of script names for a policy (production) that has a schedule (fulls):

```
/usr/openv/netbackup/bin/bpstart_notify.production
/usr/openv/netbackup/bin/bpstart notify.production.fulls
```

The first script affects all scheduled backups in the policy that are named production. The second script affects scheduled backups in the policy that is named production only when the schedule is named fulls.

Note: For a given backup, NetBackup uses only one <code>bpstart_notify</code> script and that is the script with the most specific name. For example, if there are both <code>bpstart_notify.production</code> and <code>bpstart_notify.production.fulls</code> scripts, NetBackup uses only <code>bpstart_notify.production.fulls</code>.

The bpstart notify script can use the following environment variables:

BACKUPID UNIXBACKUPTIME BACKUPTIME

The NetBackup bpbkar process creates these variables. The following are examples of the strings that are available to the script to use to record information about a backup:

BACKUPID=client1_0857340526 UNIXBACKUPTIME=0857340526 BACKUPTIME=Sun Mar 2 16:08:46 2016

In addition, the following environment variables can be used to support multiple data streams.

Environment variable	Description
STREAM_NUMBER	Specifies the stream number. The first stream from a policy, client, and schedule is 1. A 0 value indicates that multiple data streams are not enabled.
STREAM_COUNT	Specifies the total number of streams to be generated from this policy, client, and schedule.
STREAM_PID	Specifies the PID (process ID) number of bpbkar.
RESTARTED	Specifies the checkpointed restarts or checkpointed backup jobs. A value of 0 indicates that the job was not resumed. (For example, upon first initiation.) A value of 1 indicates that the job was resumed.

Table 5-5 Environment variables used to support multiple data streams

bpstart_notify.bat script (Windows clients)

For all Windows clients, you can create batch scripts that provide notification whenever the client starts a backup or archive.

To use this script, copy the following file from the server:

On Windows:

Install_path\NetBackup\bin\goodies\bpstart_notify.bat

Then place the file on the client in the same directory as the NetBackup client binaries:

Install_path\NetBackup\bin\

Where *Install_path* is the directory where NetBackup is installed.

You can create <code>bpstart_notify</code> scripts that provide notification for all backups or for backups of a specific policy or schedule.

To create a script that applies to all backups, name the script <code>bpstart notify.bat</code>.

To create a <code>bpstart_notify</code> script that applies only to a specific policy or policy and schedule combination, add a *.policyname* or *.policyname.schedulename* suffix to the script name.

The following are examples of bpstart notify script names:

The following script applies only to a policy named days:

install_path\netbackup\bin\bpstart_notify.days.bat

 The following script applies only to a schedule that is named *fulls* in a policy named days:

install_path\netbackup\bin\bpstart_notify.days.fulls.bat

The bpstart_notify script also runs for NetBackup catalog backups if a
.policyname[.schedule] is not specified.

The first script affects all scheduled backups in the policy named days. The second script affects scheduled backups in the policy named days only when the schedule is named fulls.

For a given backup, NetBackup calls only one <code>bpstart_notify</code> script and checks for them in the following order:

```
bpstart_notify.policy.schedule.bat
bpstart_notify.policy.bat
bpstart_notify.bat
```

For example, if there are both <code>bpstart_notify.policy.bat</code> and <code>bpstart_notify.policy.schedule.bat</code> scripts, NetBackup uses only the <code>bpstart_notify.policy.schedule.bat</code> script.

Note: <code>bpend_notify</code> scripts can provide a different level of notification than the <code>bpstart_notify</code> scripts. For example, to use one of each, the script names might be <code>bpstart_notify.policy.bat</code> and <code>bpend_notify.policy.schedule.bat</code>.

NetBackup passes the following parameters to the script:

- %1 Specifies the name of the client from the NetBackup catalog.
- %2 Specifies the policy name from the NetBackup catalog.
- %3 Specifies the schedule name from the NetBackup catalog.
- %4 Specifies one of the following: FULL, INCR, CINC, UBAK, UARC
- %5 Specifies that the status of the operation is always 0 for <code>bpstart notify</code>.
- %6 Specifies the results file that NetBackup checks for a return code from the script. NetBackup uses %6 to pass the file name and then expects the script to create the file in the same directory as the script.

If the script applies to a specific policy and schedule, the results file must be named

install path\netbackup\bin\BPSTART RES.policy.schedule

If the script applies to a specific policy, the results file must be named

install path\netbackup\bin\BPSTART RES.policy

If the script applies to all backups, the results file must be named

install_path\netbackup\bin\BPSTART_RES

An echo 0> %6 statement is one way for the script to create the file.

NetBackup deletes the existing results file before it calls the script. After the script runs, NetBackup checks the new results file for the status. The status must be 0 for the script to be considered successful. If the results file does not exist, NetBackup assumes that the script was successful.

The server expects the client to respond with a continue message within the time that the BPSTART_TIMEOUT option specifies on the server. The default for BPSTART_TIMEOUT is 300 seconds. If the script needs more time than 300 seconds, increase the value to allow more time. (The BPSTART_TIMEOUT option corresponds to the **Backup start notify timeout** on the **Timeouts** host properties.)

Note: The Client read timeout (CLIENT_READ_TIMEOUT option) must be equal to or greater than the Backup start notify timeout (BPSTART_TIMEOUT option). If the Client read timeout is less than the Backup start notify timeout, the job can timeout while the bpstart_notify script is running.

bpend_notify script (UNIX clients)

To receive a notification whenever a UNIX client completes a backup or an archive operation, copy the following file from the server:

On Windows:

Install_path\NetBackup\bin\goodies\bpend_notify

On UNIX:

/usr/openv/netbackup/bin/goodies/bpend notify

Then place the file in the following location on the UNIX client:

/usr/openv/netbackup/bin/bpend notify

Modify the script and ensure that you have permission to run the script.

Note: The <code>bpend_notify</code> script is run when the client is finished sending data, but the server has not yet completed writing to media.

Note: Ensure that other administrators can run the notify scripts after they are modified. To do so, run chmod ugo+rx script_name, where script_name is the name of the script.

The <code>bpend_notify</code> script runs each time a backup or archive completes. For archives, it runs after the backup but before the files are removed.

If <code>bpend_notify</code> exists, it runs in the foreground and <code>bpbkar</code> on the client waits until it completes. Any commands that do not end with an ampersand character (&) run serially.

The server expects the client to respond within the time that the BPEND_TIMEOUT NetBackup configuration option specifies. The default for BPEND_TIMEOUT is 300.

If the script needs more than 300 seconds, set BPEND_TIMEOUT to a larger value. Avoid too large a value because it can delay the server from servicing other clients.

clientname	Specifies the name of the client from the NetBackup catalog.
policyname	Specifies the policy name from the NetBackup catalog.
schedname	Specifies the schedule name from the NetBackup catalog.

schedtype	Specifies one of the following: FULL, INCR (differential incremental), CINC (cumulative incremental), UBAK, UARC
exitstatus	Specifies the exit code from ${\tt bpbkar}.$ The status is the client status and does not indicate that the backup is complete and successful.
	The client can display a status 0 when, due to a failure on the server, the All Log Entries report displays a status 84.

Note: The bpend_notify script also runs for NetBackup catalog backups if a .policyname[.schedule] is not specified.

For example:

```
bpend_notify client1 pol_1 fulls FULL 0
bpend notify client2 pol 1 incrementals INCR 73
```

To create a <code>bpend_notify</code> script for a specific policy or policy and schedule combination, create script files with a .policyname or .policyname.schedulename suffix. The following are two examples of script names for a policy that is named production with a schedule that is named fulls:

```
/usr/openv/netbackup/bin/bpend_notify.production
/usr/openv/netbackup/bin/bpend_notify.production.fulls
```

The first script affects all scheduled backups in the policy production. The second script affects scheduled backups in the policy production only when the schedule is named fulls.

Note: For a given backup, NetBackup uses only one bpend_notify script and that is the one with the most specific name. For example, if there are both bpend_notify.production and bpend_notify.production.fulls scripts, NetBackup uses only bpend_notify.production.fulls.

The bpend notify script can use the following environment variables:

BACKUPID UNIXBACKUPTIME BACKUPTIME

The NetBackup bpbkar process creates these variables. The following are examples of the strings that are available to the script for use to record information about a backup:

```
BACKUPID=client1_0857340526
UNIXBACKUPTIME=0857340526
BACKUPTIME=Sun Mar 2 16:08:46 2011
```

The following environment variables can be used for the support of multiple data streams.

Table 5-6 Environment variables used for support of multiple data s

Environment variable	Description
STREAM_NUMBER	Specifies the stream number. The first stream from a policy, client, and schedule is 1. A 0 value indicates that multiple data streams are not enabled.
STREAM_COUNT	Specifies the total number of streams to be generated from this policy, client, and schedule.
STREAM_PID	Specifies the PID (process ID) number of bpbkar.
FINISHED	Specifies the status of the checkpointed restarts of backup jobs. A value of 0 indicates that the client was not finished sending all of the data. A value of 1 indicates that the client was finished sending all of the data.

bpend_notify.bat script (Windows clients)

For Windows clients, you can create batch scripts that provide notification whenever the client completes a backup or archive. These scripts must reside on the client and in the same directory as the NetBackup client binaries:

Install_path\NetBackup\bin\bpend_notify.bat

Install_path is the directory where NetBackup is installed.

You can create bpend_notify scripts that provide notification for all backups or for backups of a specific policy or schedule.

To create a <code>bpend_notify</code> script that applies to all backups, name the script bpend notify.bat

To create a script that applies only to a specific policy or policy and schedule combination, add a *.policyname* or *.policyname.schedulename* suffix to the script name as follows:

The following script applies only to a policy named days:

Install_path\netbackup\bin\bpend_notify.days.bat

 The following script applies only to a schedule that is named fulls in a policy named days: Install_path\netbackup\bin\bpend_notify.days.fulls.bat

Note: The bpend_notify script also runs for NetBackup catalog backups if a .policyname[.schedule] is not specified.

The first script affects all scheduled backups in the policy named days. The second script affects scheduled backups in the policy named days only when the schedule is named fulls.

For a given backup, NetBackup calls only one <code>bpend_notify</code> script and checks for them in the following order:

bpend_notify.policy.schedule.bat
bpend_notify.policy.bat
bpend_notify.bat

For example, if there are both bpend_notify.policy.bat and bpend_notify.policy.schedule.bat scripts, NetBackup uses only bpend_notify.policy.schedule.bat.

Note: <code>bpstart_notify</code> scripts can provide a different level of notification than the <code>bpend_notify</code> scripts. For example, if you had one of each, they could be <code>bpstart_notify.policy.bat</code> and <code>bpend_notify.policy.schedule.bat</code>.

NetBackup passes the following parameters to the script when the backup completes:

- %1 Specifies the name of the client from the NetBackup catalog.
- %2 Specifies the policy name from the NetBackup catalog.
- %3 Specifies the schedule name from the NetBackup catalog.
- %4 Specifies one of the following: FULL, INCR, CINC, UBAK, UARC
- %5 Specifies the status of the operation. It is the same status as is sent to the NetBackup server. The status is 0 for successful backups and 1 for partially successful backups. If an error occurs, the status is the value associated with that error.

%6 Specifies the results file that NetBackup checks for a return code from the script. NetBackup uses %6 to pass the file name and then expects the script to create the file in the same directory as the script.

If the script applies to a specific policy and schedule, the results file must be named

Install_path\netbackup\bin\BPEND_RES.policy.schedule

If the script applies to a specific policy, the results file must be named

Install_path\netbackup\bin\BPEND_RES.policy

If the script applies to all backups, the results file must be named

Install_path\netbackup\bin\BPEND_RES

An echo 0> %6 statement is one way for the script to create the file.

NetBackup deletes the existing results file before it calls the script. After the script runs, NetBackup checks the new results file for the status. The status must be 0 for the script to be considered successful. If the results file does not exist, NetBackup assumes that the script was successful.

The server expects the client to respond with a continue message within the time that the BPEND_TIMEOUT option specifies. The default for BPEND_TIMEOUT is 300. If the script needs more than 300 seconds, increase the value to allow more time.

bpend_notify_busy script (UNIX clients)

Use the <code>bpend_notify_busy</code> script to configure busy file processing when using the <code>bp.conf</code> file.

See "About busy file processing on UNIX clients" on page 66.

Busy file processing can also be configured in the **Busy File Settings** host properties of the **NetBackup Administration Console**.

diskfull_notify script

The diskfull_notify.cmd script (on Windows) and the diskfull_notify script (on UNIX) run on the NetBackup server that contains the storage unit. The disk media manager (bpdm) calls this script if it encounters a disk full condition while it writes a backup to a disk storage unit. The default action is to report the condition and immediately try to write the data again. (The file being written is kept open by the active bpdm).

The scripts are located in the following directories:

On Windows: Install path\NetBackup\bin\diskfull notify.cmd

On UNIX: /usr/openv/netbackup/bin/diskfull_notify

The script can be modified to send a notification to an email address or modified to perform actions such as removing other files in the affected directory or file system.

NetBackup passes the following parameters to the script:

programname Specifies the name of the program (always bpdm).

pathname Specifies the path to the file being written.

For example:

/disk1/images/host 08193531 c1 F1

See the following Windows example:

diskfull notify.cmd bpdm

drive_mount_notify script (on UNIX)

The NetBackup tpreq command runs the drive_mount_notify script (if it exists) immediately after media is mounted in a pre-selected, robotic drive. This script is not valid for standalone drives.

Each time a tape volume is mounted, this script gathers information on the drive that is mounted. This script also lets you perform special-handling. For example, you can use the script to gather log sense or other data from a drive and place it in an output file. You can change the information that the script gathers by modifying the script.

After the script runs, control is then returned to NetBackup to resume processing.

This script is located in the following directory:

/usr/openv/volmgr/bin/goodies

To use this script, activate it and place it into the /usr/openv/volmgr/bin directory. See the script for instructions about how to activate it and how to modify it.

drive_unmount_notify script (on UNIX)

The NetBackup tpunmount command runs the drive_unmount_notify script (if it exists) after media is unmounted. This script is valid for robotic drives and standalone drives.

Each time a tape volume is unmounted, this script gathers information about the drive that is unmounted. This script also lets you perform special-handling. For example, you can use the script to gather log sense or other data from a drive and place it in an output file. You can change the information that the script gathers by modifying the script.

After the script runs, control is then returned to NetBackup to resume processing.

This script is located in the following directory:

/usr/openv/volmgr/bin/goodies

To use this script, activate it and place it into the /usr/openv/volmgr/bin directory. See the script for instructions about how to activate it and how to modify it.

mail_dr_info script

Use the mail_dr_info.cmd script (on Windows) and the mail_dr_info.sh script (on UNIX) to send NetBackup disaster recovery information to specified recipients after running an online, hot catalog backup.

By default, this script does not exist. You must create it. How you do so depends on the operating system type of your master server.

On Windows: To create the script, copy the following script from the master server:

Install path\NetBackup\bin\goodies\nbmail.cmd

and place it into the following location:

Install path\NetBackup\bin\mail dr info.cmd.

On UNIX: To create the script, touch the following file:

/usr/openv/netbackup/bin/mail_dr_info.sh

NetBackup passes the following parameters to the script:

- %1 Specifies the recipient's address. For multiple addresses, enter email1,email2
- %2 Specifies the subject line.
- %3 Specifies the message file name.
- %4 Specifies the attached file name.

On Windows: NetBackup checks to see if mail_dr_info.cmd is present in Install_path\NetBackup\bin. If mail_dr_info.cmd exists, NetBackup passes
the parameters to the script. **Note:** All NetBackup email notifications require that a public domain SMTP mail client be configured. (For example, blat.) For details, see the comments in the nbmail.cmd script.

On UNIX: NetBackup checks to see if mail_dr_info.sh is present in /usr/openv/netbackup/bin. If mail_dr_info.cmd exists, NetBackup passes the parameters to the script.mail_dr_info.sh is not an installed file. Users must create the script.

media_deassign_notify script

The NetBackup Media Manager calls the media_deassign_notify script after media is deassigned. To send an email notification when media is deassigned, include an email address in the script where indicated. (The script must be run as the root user.)

On Windows: Copy

Install_path\NetBackup\bin\goodies\media_deassign_notify.cmd into
Install path\NetBackup\bin\ on the master server.

On UNIX: Copy /usr/openv/netbackup/bin/goodies/media_deassign_notify into /usr/openv/netbackup/bin/ on the master server.

If the script exists in the \bin directory, the following parameters are passed to the script: media ID, legacy media type, barcode, robot number, and robot type.

nbmail.cmd script (on Windows)

Use the nbmail.cmd script to send the specified recipients notifications about scheduled backups. The recipients' email addresses must also be configured in the **Universal Settings** host properties.

Windows systems also require that you install the Simple Mail Transfer Protocol application to transfer messages to accept script parameters. UNIX platforms have a built-in SMTP transfer method.

To create the script on a client, copy

Install_path\NetBackup\bin\goodies\nbmail.cmd from the master server into Install path\NetBackup\bin of each client that is to receive the notification.

- %1 Specifies the address of the recipient. For multiple addresses, enter email1, email2
- %2 Specifies the contents of the subject line.

- %3 Specifies the file that is sent in the body of the email. This is generated by another script.
- %4 Specifies the attached file name.

NetBackup checks to see if nbmail.cmd is present in *Install_path*\NetBackup\bin. If nbmail.cmd exists, NetBackup passes the parameters to the script.

parent_end_notify script

NetBackup calls the parent_end_notify.cmd script (on Windows) and the parent end notify script (on UNIX) each time a parent job ends.

NetBackup passes the following parameters to the script:

clientname	Specifies the name of the client from the NetBackup catalog.
policyname	Specifies the policy name from the NetBackup catalog.
schedname	Specifies the schedule name from the NetBackup catalog.
schedtype	Specifies one of the following: FULL, INCR (differential incremental), CINC (cumulative incremental), UBAK, UARC
status	Specifies the exit code for the entire backup job.
stream	Specifies the stream number; it's always -1.
stream_count	Specifies that if the job starts normally, the stream count indicates how may streams were started.
	Verifies the number of streams that complete and run backup_exit_notify. If a failure occurs that makes it impossible to start any streams, a stream count of -1 is returned.

parent_start_notify script

NetBackup calls the parent_start_notify.cmd script (on Windows) or the parent start notify script (on UNIX) each time a parent job starts.

clientname	Specifies the name of the client from the NetBackup catalog.
policyname	Specifies the policy name from the NetBackup catalog.
schedname	Specifies the schedule name from the NetBackup catalog.

schedtype	Specifies one of the following: FULL, INCR (differential incremental), CINC (cumulative incremental), UBAK, UARC
status	Specifies the exit code for the entire backup job.
streamnumber	Specifies the stream number; for a parent job it's always -1.

pending_request_notify script

The NetBackup Media Manager calls the pending_request_notify script after a pending request is issued for a media resource (tape volume). To send an email notification when a pending request is initiated, include an email address in the script where indicated. (A root user must run the script.)

On Windows: Copy

Install_path\NetBackup\bin\goodies\pending_request_notify.cmd into
Install path\NetBackup\bin\ on the master server.

On UNIX: Copy /usr/openv/netbackup/bin/goodies/pending_request_notify into /usr/openv/netbackup/bin/ on the master server.

If the script exists in the /bin directory, the following parameters are passed to the script: media ID, barcode, action code, robot type, robot number, media server, volume group, and pending time (in seconds since the UNIX epoch).

restore_notify script

The restore_notify.cmd script (on Windows) and the restore_notify script (on UNIX) run on the server that contains the storage unit. The NetBackup tape or disk manager (bptm or bpdm) calls the script when it finishes sending data to the client during a restore. The script is called regardless of whether data is sent.

The scripts are located in the following directories:

On Windows: Install_path\NetBackup\bin\restore_notify.cmd

On UNIX: /usr/openv/netbackup/bin/restore_notify

programname	Specifies the name of the program doing the restore or other read operation.
pathname	Specifies the path to the backup name or path.
operation	Specifies one of the following: <code>restore</code> , <code>verify</code> , <code>duplication</code> , <code>import</code>

session_notify script

The session_notify.cmd script (on Windows) and the session_notify script (on UNIX) run on the master server. It's called at the end of a backup session if at least one scheduled backup succeeded. NetBackup passes no parameters to this script. Scheduling is suspended until this script completes, so no other backups can start until that time.

The scripts are located in the following directories:

On Windows: Install path\NetBackup\bin\session notify.cmd

On UNIX: /usr/openv/netbackup/bin/session_notify

session_start_notify script

The session_start_notify.cmd script (on Windows) and the
session_start_notify script (on UNIX) run on the master server. When a set of
backups is due to run, NetBackup calls this script to do any site-specific processing
before it starts the first backup. NetBackup passes no parameters to this script.

The scripts are located in the following directories:

On Windows: *Install_path*\NetBackup\bin\session_start_notify.cmd

On UNIX: /usr/openv/netbackup/bin/session_start_notify

shared_drive_notify script

NetBackup runs the shared_drive_notify.cmd script (on Windows) and the
shared drive notify script (on UNIX) when a shared drive is reserved or released.

- The name of the shared drive.
- The name of the current scan host.
- The operation, which is one of the following:

RESERVED	Specifies that the host on which the script is executed needs SCSI access to the drive until it's released.
ASSIGNED	Informational only. Specifies that the host that reserved the drive needs SCSI access.
RELEASED	Specifies that only the scan host needs SCSI access to the drive.

SCANHOST Specifies that the host that executes the script has become the scan host. A host should not become a scan host while the drive is RESERVED.

The scan host may change between a RESERVED operation and a RELEASED operation.

The scripts are located in the following directories:

On Windows: Install path\Volmgr\bin\shared drive notify.cmd

On UNIX: /usr/openv/volmgr/bin/shared drive notify

The script must be executable by the root user.

The script exits with status 0 upon successful completion.

userreq_notify script

The $userreq_notify.cmd$ script (on Windows) and the $userreq_notify$ script (on UNIX) run on the master server.

The scripts are located in the following directories:

On Windows: Install path\NetBackup\bin\userreq notify.cmd

On UNIX: /usr/openv/netbackup/bin/userreq notify

NetBackup calls the script each time a request is made to either of the following:

- List files that are in backups or archives
- Start a backup, archive, or restore

You can change this script to gather information about user requests to NetBackup.

NetBackup passes the following parameters to the script:

action	Specifies the action and can have the following values: backup,	
	archive, manual_backup, restore, list	
clientname	Specifies the client name.	
userid	Specifies the user ID.	

See the following UNIX example:

userreq_notify backup mercury jdoe
userreq_notify archive mercury jdoe
userreq notify manual backup mercury jdoe

```
userreq_notify restore mercury jdoe
userreq notify list mercury jdoe
```

Media and device management best practices

Use the following best practices for NetBackup media and device management. Follow these recommendations to minimize problems and to reduce the time and the effort that is required to administer the configuration.

For a list of supported devices, server platforms, and the latest device mapping file, see the NetBackup website:

http://www.netbackup.com/compatibility

The following items are general best practices for media and device management:

- Use only the NetBackup commands that Veritas documents and supports.
- Refer to the NetBackup release notes for configuration and operational changes in the current release or in future releases. The release notes also contain information about all new functionality in each release.
- Use the documented methods for terminating the NetBackup Media Manager daemons and services.
- Periodically verify the backups by using NetBackup Management > Catalog in the NetBackup Administration Console. Also, periodically restore the files to prove that restores work correctly.
- Always back up the NetBackup catalogs. You may also want to back up the vm.conf file and the bp.conf (UNIX system) files on the media servers.
- When you restore the NetBackup catalog (for example, master server databases and the EMM database), use backups from the same point in time.
- Ensure that all names and numbers for devices and all media IDs and barcodes are unique across the entire enterprise.
- On UNIX hosts: To use the devices that NetBackup controls but are used with other applications, do the following to avoid the potential loss of data:
 - Use the NetBackup tpreq command to mount media on a drive and tpunmount to remove media from the drive. If you use these commands, another application can control a device when NetBackup is finished with the device.
 - Down the drive, if the drive is in the UP state.
- On Windows hosts: To use the devices that NetBackup controls but are used with other applications, down the drive if the drive is in the UP state.

Media management best practices

The following items are NetBackup media management best practices:

- Use the robot inventory update operation for media management.
- Use a scratch pool for unassigned media.
- Configure cleaning cartridges for tape drives and use TapeAlert for automatic drive cleaning if the drives support automatic cleaning.
- Replace old media according to the life-span recommendations of the manufacturer. Replace old cleaning media also.
- Use the robotic libraries that have a bar code reader and use only the bar code labels that the robot vendor recommends.
- Use bar code rules for media type assignment when you inventory multimedia libraries. Use bar code naming conventions to differentiate between data and cleaning tapes and different physical media types. A common convention is a prefix that identifies the type of media.
- Before performing inject or eject commands, ensure that the media access port is empty. Although NetBackup can handle a port that is not empty, some libraries can have problems.

Device management best practices

The following items are device management best practices:

- Monitor the NetBackup system log for device errors encountered.
- Monitor devices by using the NetBackup Device Monitor.
- Investigate the causes of all the drives that are down.
- Do not use the robotic test utilities while running backup or restore jobs.
- Read the NetBackup Device Configuration Guide before configuring devices on media servers (or SAN media servers). See the NetBackup Device Configuration Guide at the following URL: http://www.veritas.com/docs/DOC5332
- Use only computers, operating systems and devices that Veritas supports. For supported devices, see the NetBackup hardware compatibility list on the NetBackup support site.
- Use only fully-serialized devices. A fully-serialized SCSI library should report a serial number for the robot and also a serial number for each drive in the robot.
- Always configure and use pass-through paths for robotic libraries and drives.

- When possible, use SCSI persistent reserve or SCSI reserve and release.
- Use persistent bindings for fibre-attached devices.
- Use the NetBackup Device Configuration Wizard to configure the devices.
- Download and install the latest device mapping file from the NetBackup support Web site before you use the NetBackup Device Configuration Wizard.
- Use consistent logical drive types for all physical drive types on all servers in the environment. For example, use the DLT drive type as the logical drive type for all DLT7000 drives.
- Do not load vendor medium-changer drivers on Microsoft Windows hosts. The default Microsoft medium-changer driver is acceptable (but is not required) for use with NetBackup.

Media and device performance and troubleshooting

The following items are performance and troubleshooting best practices:

- Use the performance-tuning documents available on the NetBackup support Web page.
- Use only a dedicated server for the NetBackup master server. Do not use a server that hosts other applications or one that stores data. Plan periodic maintenance for all of the backup servers.
- Consult the Troubleshooter in the NetBackup Administration Console or the NetBackup Status Codes Reference Guide for all error conditions: http://www.veritas.com/docs/DOC5332
- Always install the latest NetBackup release updates that are available from Veritas.
- Verify all SCSI-related operating system configuration files (such as the Solaris st.conf file), when you install system release updates.
- For problems with devices, consult the vendor for firmware upgrades and consult the NetBackup hardware compatibility list for supported firmware levels.
- **Do not use the NetBackup** DISABLE_RESOURCES_BUSY **touch file**.
- Do not disable the operating system TCP_NODELAY functionality.

About TapeAlert

TapeAlert is a tape drive status monitor and message utility. The TapeAlert utility can detect tape quality problems, defects in tape drive hardware, and the need to clean drives. For the tape drives that support TapeAlert, the TapeAlert firmware

monitors the drive hardware and the media. Error, warning, and informational states are logged on a TapeAlert log page.

For the drives that do not support TapeAlert, configure and use frequency-based cleaning.

See "About frequency-based cleaning" on page 172.

About TapeAlert cleaning (reactive cleaning)

Reactive cleaning by using TapeAlert is a function of the tape drive. The drive determines and initiates the cleaning when needed. If a drive supports the TapeAlert capability and it is enabled on the drive, the NetBackup bptm process polls the drive for status from TapeAlert.

TapeAlert allows reactive cleaning for most drive types. Not all platforms, robots, drives, or firmware levels support TapeAlert reactive cleaning.

A drive with TapeAlert capability tracks how many read and write errors it has encountered within a certain time period. Although a drive can recover from these errors, the drive sets a CLEAN_NOW or CLEAN_PERIODIC flag when a threshold is reached.

If the bptm process detects that either of the following flags are set, it performs a cleaning at one of the following times:

- At the end of a backup or a restore to the drive.
- Before the next backup or restore to the drive.

Veritas recommends that you use reactive cleaning.

See "About TapeAlert" on page 166.

See "About tape drive cleaning" on page 171.

About TapeAlert and frequency-based cleaning

Using TapeAlert with frequency-based cleaning ensures that a drive is cleaned at least every *x* hours, depending on the setting for the cleaning frequency. In addition, the drive can be cleaned sooner if the drive sets the CLEAN_NOW or CLEAN_PERIODIC TapeAlert flag.

When TapeAlert is used without frequency-based cleaning, a drive is cleaned only when the drive sets its CLEAN_NOW or CLEAN_PERIODIC flags.

About TapeAlert requirements

To use TapeAlert, all of the following conditions must be true:

- The host platform, robot type, and drive support drive cleaning.
- The drive must support the TapeAlert capability, and the TapeAlert are enabled on the drive.

To determine if a drive supports TapeAlert, see the Veritas Support website.

- A cleaning tape is configured and available in NetBackup for the robotic library. The cleaning cartridge is compatible with the drive that needs to be cleaned.
- The cleaning tape has not reached its end of life.
- Pass through device files are configured on UNIX media servers.
 See the NetBackup Device Configuration Guide, available at the following URL: http://www.veritas.com/docs/DOC5332

TapeAlert logs and codes

TapeAlert codes are derived from the T10 SCSI-3 Stream Commands standard (see http://t10.org/). For the list of codes that the device supports, see the device's documentation.

TapeAlert checks for errors of the following types:

- Recoverable read and write drive problems
- Unrecoverable read and write drive problems
- Hardware defects
- Wrong or worn-out media
- Expired cleaning tapes
- Abnormal errors

A set of TapeAlert conditions is defined that can cause the media in use to be frozen. Another set of conditions are defined that can cause a drive to be downed.

NetBackup writes TapeAlert conditions into the following logs:

- The bptm log
- The error log
- The job details log
- The system log on UNIX and Event Viewer on Windows

The following table describes the codes.

TapeAlert code	Default action	Error type	Error message
0x01	None	Warning - WRN	Read warning
0x02	None	Warning - WRN	Write warning
0x03	None	Warning - WRN	Hard error
0x04	Freeze media - FRZ	Critical - CRT	Media
0x05	Freeze media - FRZ	Critical - CRT	Read failure
0x06	Freeze media - FRZ	Critical - CRT	Write failure
0x07	Freeze media - FRZ	Warning - WRN	Media life
0x08	Freeze media - FRZ	Warning - WRN	Not data grade
0x09	None	Critical - CRT	Write protect
0x0a	None	Informational - INFO	No removal
0x0b	None	Informational - INFO	Cleaning media
0x0c	None	Informational - INFO	Unsupported format
0x0d	Freeze media - FRZ	Critical - CRT	Recoverable mechanical cartridge failure
0x0e	Freeze media - FRZ	Critical - CRT	Unrecoverable mechanical cartridge failure
0x0f	Freeze media - FRZ	Warning - WRN	Mic failure
0x10	None	Critical - CRT	Forced eject
0x11	None	Warning - WRN	Read only
0x12	None	Warning - WRN	Directory corrupted on load
0x13	Freeze media - FRZ	Informational - INFO	Nearing media life
0x14	Clean drive - CLN	Critical - CRT	Clean now
0x15	Clean drive - CLN	Warning - WRN	Clean periodic

 Table 5-7
 TapeAlert log codes

		····,	
TapeAlert code	Default action	Error type	Error message
0x16	Freeze media - FRZ	Critical - CRT	Expired cleaning media
0x17	Freeze media - FRZ	Critical - CRT	Invalid cleaning tape
0x18	None	Warning - WRN	Retension requested
0x19	None	Warning - WRN	Dual-port error
0x1a	None	Warning - WRN	Cooling fan failure
0x1b	None	Warning - WRN	Power supply failure
0x1c	None	Warning - WRN	Power consumption
0x1d	None	Warning - WRN	Drive maintenance
0x1e	Down drive - down	Critical - CRT	Hardware A
0x1f	Down drive - DOWN	Critical - CRT	Hardware B
0x20	None	Warning - WRN	Interface
0x21	None	Critical - CRT	Eject media
0x22	None	Warning - WRN	Download fail
0x23	None	Warning - WRN	Drive humidity
0x24	None	Warning - WRN	Drive temperature
0x25	None	Warning - WRN	Drive voltage
0x26	None	Critical - CRT	Predictive failure
0x27	None	Warning - WRN	Diagnostics req.
0x28 - 0x31	None	Informational - INFO	Undefined
0x32	None	Warning - WRN	Lost statistics
0x33	Freeze media - FRZ	Warning - WRN	Directory invalid on unload
0x34	Freeze media - FRZ	Critical - CRT	System area write failure
0x35	Freeze media - FRZ	Critical - CRT	System area read failure

 Table 5-7
 TapeAlert log codes (continued)

TapeAlert code	Default action	Error type	Error message
0x36	Freeze media - FRZ	Critical - CRT	No start of data
0x37	Freeze media - FRZ	Critical - CRT	Loading failure
0x38	Freeze media - FRZ	Critical - CRT	Unrecoverable unload failure
0x39	None	Critical - CRT	Automation interface failure
0x3a	None	Warning - WRN	Firmware failure
0x3d - 0x40	None	Informational - info	Undefined

 TapeAlert log codes (continued)

About tape drive cleaning

The following types of drive cleaning are available by using NetBackup:

Reactive cleaning	See "About TapeAlert cleaning (reactive cleaning)" on page 167.
	Veritas recommends that you use reactive cleaning.
Library-based cleaning	See "About library-based cleaning" on page 171.
Frequency-based cleaning	See "About frequency-based cleaning" on page 172.
Operator-initiated cleaning	See "About operator-initiated cleaning" on page 172.

See "About using a cleaning tape" on page 173.

About library-based cleaning

NetBackup does not support library-based cleaning for most robots because robotic library and operating systems vendors implement this cleaning in different ways. (Library-based cleaning also is known as robotic cleaning or auto cleaning.) These different methods often interfere with NetBackup robotic control operations.

NetBackup does not define the cleaning media that is used for library-based cleaning, and the robotic library manages the cleaning media.

Because TapeAlert provides the same type of cleaning as library-based cleaning, Veritas recommends disabling library-based cleaning when you use TapeAlert.

About frequency-based cleaning

Frequency-based cleaning occurs when the accumulated mount time exceeds the time you specify for the cleaning frequency. NetBackup updates the mount time for the drive each time a tape is unmounted.

The cleaning frequency is configured when a drive is added to NetBackup. Change the cleaning frequency by changing the drive properties or by using the **Media and Device Management Device Monitor** in the **NetBackup Administration Console**.

If the following conditions are met, drive cleaning occurs when the accumulated mount time exceeds the time specified for the cleaning frequency:

- The drive is in a robotic library that supports drive cleaning.
- A cleaning tape is configured and available for the robotic library.
- The cleaning tape has cleanings remaining.

NetBackup cleans the drive immediately after a tape is unmounted. Drive cleaning does not unmount a drive in the middle of an active backup. The mount time is reset after the drive is cleaned. The cleaning frequency value remains the same.

A cleaning can occur within a backup if the backup spans tapes. For example, if cleaning is due after the first tape is full, NetBackup cleans the drive before it mounts the next tape.

Media can remain in a drive for extended periods. It does not affect the cleaning frequency because NetBackup increments the mount time only when NetBackup assigns the media to a process.

Frequency-based cleaning is not supported for drives in the ACS or the TLH libraries that are under API robotic control. The robotic library software controls the drive cleaning. To manage drive cleaning for these robots, use the robot vendor interfaces.

See "About TapeAlert and frequency-based cleaning" on page 167.

See "About tape drive cleaning" on page 171.

About operator-initiated cleaning

A drive cleaning can be initiated regardless of the cleaning frequency or accumulated mount time of the drive. Clean standalone drives or robotic drives if a cleaning tape of the correct media type and residence for the drive was added to NetBackup.

NetBackup reports that a drive needs cleaning if either of the following conditions are true:

- The value for the mount time is greater than the cleaning frequency.
- The TapeAlert CLEAN_NOW or CLEAN_PERIODIC flag is set.

And either of the following conditions must be true:

- The drive is a standalone drive and a cleaning tape is not defined.
- The drive is a standalone drive and no cleaning tape has any cleanings that remain.

NetBackup displays NEEDS CLEANING as follows:

- The Tape Cleaning Comment column of the Drive List in the Devices node of the NetBackup Administration Console.
- The comment field of the output from the tpclean -L command.

About using a cleaning tape

You can specify the number of cleanings that are allowed for a cleaning tape. This number is reduced with each cleaning. When the number of cleanings is zero, NetBackup stops by using the cleaning tape. Then, use a new cleaning tape or increase the number of cleanings that are allowed for the tape.

Note: NetBackup does not control the cleaning tapes that library-based cleaning uses.

Veritas suggests following the recommendations from cleaning tape vendors for the amount of tape usage. If you clean a tape past its recommended life, cleaning delays can occur (due to excessive tape position operations) and drives can be downed.

How NetBackup selects drives

NetBackup stores media information and device configuration and status information in the EMM database. When a robotic mount request is issued, the NetBackup Resource Broker (nbrb) queries the EMM database for the media ID of the volume requested. If the volume is in the EMM database, the media request is matched with a compatible drive in the robot. The mount request is forwarded to the appropriate robotic daemon (UNIX) or process (Windows) based on the location of the media. Location is the robotic library and the storage slot number, if applicable.

A drive must meet the following criteria to be selected for the mount request:

- The drive is configured.
- The drive is in the robotic library that contains the media.
- The drive allows the requested media density.

The EMM service (nbemm) manages the drives and requests for locally-attached or shared drives in the EMM domain.

The EMM service manages the drives by doing the following actions:

Determines which of the drives are currently available.

A drive is available if it is one of the following:

- Configured as UP
- Not assigned
- Compatible with the media type
- Not reserved by another host
- Picks an available drive that was least recently used.
 NetBackup selects the robotic-based drives over standalone drives unless the

correct media already is loaded in a standalone drive.

The first drive in the drive configuration is used first, and then the second drive, and then the next. Use the tpconfig -d command to see the drive order in the configuration.

If some of the drives are shared drives, NetBackup chooses a nonshared drive first (if one is available). NetBackup chooses a shared drive first so the shared drives can be used on other hosts that share the drives. Shared drives require the Shared Storage Option.

How NetBackup reserves drives

In multiple-initiator (multiple host bus adapter) environments, device-level access protection is required to avoid unintended sharing of tape devices and possible data loss problems. (Shared Storage Option is a multiple-initiator environment.) Access protection on a tape drive prevents an HBA that is not the reservation owner from issuing commands to control the drive. SCSI access protection operates at the SCSI target level and depends on correct operation of the fiber-to-SCSI bridge or the native fiber device hardware.

The only commonly available technique for this purpose is SPC-2 SCSI reserve and release functionality. All tape drive vendors support the SPC-2 SCSI reserve method. NetBackup has used SPC-2 SCSI reserve since NetBackup 3.4.3; it is the default tape drive reservation method in NetBackup. SPC-2 SCSI reserve is effective for most NetBackup environments.

Alternatively, the new SCSI persistent reserve method may be more effective in either of the following environments because it provides device status detection and correction:

- NetBackup media servers are in a cluster environment
 NetBackup can recover and use a reserved drive after a failover (if NetBackup owns the reservation). (With SPC-2 SCSI reserve, a drive reset usually is required because the reservation owner is inoperative.)
- Environments where high drive availability is important NetBackup can resolve NetBackup drive reservation conflicts and maintain high drive availability. (SPC-2 SCSI reserve provides no method for drive status detection.)

However, the SCSI persistent reserve method is not supported or not supported correctly by all device vendors. Therefore, analyze the environment to ensure that all of the hardware supports SCSI persistent reserve correctly. NetBackup lets you configure either SCSI persistent reserve or SPC-2 SCSI reserve.

The following table describes the protection options.

Option	Description
SCSI persistent reserve	Provides SCSI persistent reserve protection for SCSI devices. The devices must conform to the SCSI Primary Commands - 3 (SPC-3) standard.
SPC-2 SCSI reserve (default)	Provides SPC-2 SCSI reserve protection for SCSI devices. The devices must conform to the reserve method and release management method in the SCSI Primary Commands - 2 standard.
No protection	Other HBAs can send the commands that may cause a loss of data to the tape drives.

Table 5-8Protection options

You can configure access protection for each NetBackup media server. The protection setting configures tape drive access protection for all tape drive paths from the media server on which the setting is configured. The media server setting for any drive path can be overridden.

SCSI reservations provide protection for NetBackup Shared Storage Option environments or any other multiple-initiator environment in which drives are shared.

About SCSI persistent reserve

The NetBackup process that reads from or writes to the media in a drive (bptm) issues SCSI persistent reserve commands to do the following:

 Register with the tape drive's device server (the server is a logical unit within a drive that processes SCSI tasks) Request an exclusive access reservation

If the tape drive's device server grants the reservation, the NetBackup process has exclusive use of the device. The reservation prevents other host bus adapters (HBAs) from issuing any commands that can cause data loss.

If the reservation fails, NetBackup fails the job.

When the NetBackup process is finished with the drive, NetBackup unloads the drive and sends a persistent reserve clear command to the drive. The command removes both the reservation and the registration.

SCSI persistent reserve also provides device status detection, which NetBackup uses to resolve reservation conflicts within NetBackup.

The reservation does not prevent other applications on the host that has the reservation from using the same device and from causing data loss. For example, if a user on the same host issues a UNIX <code>mt</code> command, the <code>mt</code> command can take control of the drive.

Also, other HBAs can clear or release a SCSI persistent reservation. Therefore, an application can clear another HBA reservation (although it should not do so).

About SCSI persistent reserve commands

When a device receives an exclusive access type SCSI persistent reservation command, it does not process commands from any other HBA. The device processes commands from another HBA only when the HBA that owns the SCSI persistent reservation clears the reservation. If an application sends a command to a reserved device, the device fails the command by returning a status of RESERVATION CONFLICT. The only exceptions to this action are several commands that cannot interfere with the reservation, such as Inquiry or Request Sense.

A device stays reserved until one of the following events occurs on the device:

- Released by the HBA that reserved it
- Power cycled (usually)
- Preempted by a SCSI persistent reserve command

About SCSI persistent reserve conflicts

NetBackup uses unique reservation keys. Therefore, NetBackup attempts to resolve conflicts with other NetBackup reservations. If a conflict exists, NetBackup sends SCSI commands to unload the drive. Based on the drive status, NetBackup tries to unload the drive again by using additional information to release or preempt the persistent reservation.

In cluster environments after a failover event, NetBackup on the active cluster node detects the persistent reservation and clears the reservation. NetBackup regains use of the drive without power-cycling the drive.

If NetBackup does not own the persistent reservation, NetBackup reports a pending status in the Device Monitor. The reservation owner must clear the reservation before NetBackup can use the drive. For example, NetBackup does not clear a NetApp persistent reservation.

About the SPC-2 SCSI reserve process

The NetBackup process issues an SPC-2 SCSI reserve command to the tape drive that contains the media. (The process can be <code>bptm, bprecover</code>, or <code>bpbackupdb</code>.) If the device is not reserved, NetBackup acquires a reservation. The drive does not process commands from any other host bus adapters (HBAs) until NetBackup releases the reservation or the reservation is broken. If the reservation fails, NetBackup fails the job.

The reservation does not prevent other applications on the host that has the reservation from using the same device and from causing data loss. For example, if a user on the same host issues a UNIX <code>mt</code> command, the <code>mt</code> command can take control of the drive.

After the NetBackup process finishes with the media, it issues an SPC-2 SCSI command to release the reservation during the unmount operation. The release frees the device for access by another HBA.

SCSI reserve does not provide a method to determine if a device is reserved. Only the reservation owner (the host bus adapter) can release the reservation. However, these limitations do not interfere with NetBackup operations in most environments.

About SPC-2 SCSI reserve commands

When a device receives an exclusive access type SCSI persistent reservation command, it does not process commands from any other HBA. The device processes commands from another HBA only when the HBA that owns the reservation issues the release command. If an application sends a command to a reserved device, the device fails the command by returning a status of RESERVATION CONFLICT. The only exceptions to this action are several commands that cannot interfere with the reservation, such as Inquiry or Request Sense.

A device stays reserved until one of the following events occurs on the device:

- Released by the HBA that reserved it
- Released by a TARGET or a LOGICAL UNIT RESET

These resets are protocol-dependent and differ between parallel SCSI and FCP (SCSI on Fibre Channel). These resets can be issued from any HBA.

- Released by Fibre Channel LOGO, PLOGO, PRLI, PRLO, or TPRLO action or failed discovery (link actions)
- Power cycled

A negative consequence of SPC-2 SCSI reserve occurs if the HBA that owns the reservation fails. A device stays reserved until the reservation is removed or broken. Only the original HBA can remove the reservation, which means the system must be available. If the HBA that owns the reservation fails, it cannot remove the reservation. Therefore, the reservation must be broken.

To break a reservation, one of the following actions must break the reservation:

- SCSI reset
- Bus device reset
- LUN device reset
- Power cycle
- Fibre Channel link actions may break reservations

SPC-2 SCSI reserve commands are mandatory for all SCSI-2 and SCSI-3 devices. See the SCSI 2 standard for a detailed description of SCSI reserve command operation and behavior.

About SCSI reservation conflicts

The NetBackup Automatic Volume Recognition process (avrd) manages access to tape devices. A properly configured NetBackup environment and properly configured tape devices should not receive a reservation conflict message from a tape drive. When avrd starts, it issues an SPC-2 SCSI release to all configured, nondisabled tape drive paths that are currently in the Up state. The command releases all devices that were SPC-2 reserved at the time of a system restart or crash. The SCSI release command returns tape devices to general availability after a system crash.

If the avrd process receives a reservation conflict message, it changes the status of the device to PEND. It also writes the following message in the system log:

Reservation Conflict status from DRIVENAME (device NUMBER)

Also, the **NetBackup Administration Console Device Monitor** or the output from the vmoprcmd command shows PEND in the Control column.

If a conflict occurs, a reservation problem can exist. If the HBA that reserves the drive is unavailable (for example, due to a system crash or hardware failure), it

cannot release the reservation. NetBackup cannot release or break an SPC-2 SCSI reservation automatically. Force a release or break the reservation to make the drive available, even for a failover server in a cluster environment.

When the conflict is resolved, the following message is written to the log:

Reservation Conflict status cleared from DRIVENAME (device NUMBER)

About forcing a release of an unavailable HBA's SPC-2 reservation

To force a release of an unavailable HBA's SPC-2 reservation, use the following NetBackup vmoprcmd command and option:

vmoprcmd -crawlreleasebyname drive name

This option requests that all hosts that are registered to use the drive issue SPC-2 SCSI release commands to the drive.

Issue the <code>vmoprcmd</code> command on the master server. Alternatively issue the command on a media server and use the -h option of the command to specify the master server. The NetBackup EMM service allocates devices (that is, the DA host or device allocation host).

Note: Use this command after a PEND status appears in the **NetBackup Administration Console Device Monitor**. However, do not issue this command during backups.

More information about using the vmoprcmd command is available.

See the NetBackup Commands Reference Guide, available at the following URL:

http://www.veritas.com/docs/DOC5332

Breaking a reservation

If you cannot release an SPC-2 SCSI reservation, try to use an operating system command that forces a device reset. A device reset breaks a reservation. The procedure depends on the operating system type.

Note: The reset operation can reset other devices in the configuration. Loss of data is also possible. Try alternate methods first to break the reservation on a device (by using switch and bridge hardware).

Lastly, if the following operating system commands cannot break the reservation, power-cycle the drive. A power cycle breaks SPC-2 SCSI drive reservations (and usually breaks SCSI persistent drive reservations).

To break an SPC-2 reservation on Solaris

- **1 Issue** mt -f *drive_path_name* forcereserve.
- 2 Issue mt -f drive path name release.

See the mt(1) man page for more information.

To break an SPC-2 reservation on HP-UX

♦ Issue st -f drive_path_name -r.

See the st(1m) man page for more information.

To break an SPC-2 reservation on AIX

Issue tctl -f drive_path_name reset.

See the ${\tt tctl}$ man page (in the IBM AIX Commands Reference) for more information.

About SCSI reserve requirements

To use SCSI persistent reserve or SPC-2 SCSI reserve, the following requirements must be met:

There must be pass through driver access to all shared drives.
 The pass through driver must be installed and all required paths must be created.
 Information about how to configure and use the pass through driver for UNIX operating systems is available.
 See the NetBackup Device Configuration Guide, available at the following URL:

http://www.veritas.com/docs/DOC5332

- You must configure the operating systems on the NetBackup media servers so they let NetBackup control SCSI persistent reserve or SPC-2 SCSI reserve.
- On HP-UX systems, disable the operating system's use of SPC-2 SCSI reserve. See the NetBackup Device Configuration Guide, available at the following URL: http://www.veritas.com/docs/DOC5332
- Depending on the tape drives, you may have to disable the operating system's use of SPC-2 SCSI reserve. AIX and Solaris may require such a change.
 See the NetBackup Device Configuration Guide, available at the following URL: http://www.veritas.com/docs/DOC5332

About SCSI reserve limitations

The NetBackup implementation of SCSI persistent reserve and SPC-2 reserve has the following limitations:

- SCSI persistent reserve and SPC-2 reserve do not apply to NDMP drives. The NDMP filer is responsible for providing exclusive device access.
- Third-party copy configurations must be configured correctly.
 To retain reservation of a tape device during a third-party copy backup, configure the NetBackup mover.conf file.

Do not use SCSI persistent reserve on the drive paths that are used for third-party copy backups.

See the *NetBackup Snapshot Client Administrator's Guide*, available at the following URL:

http://www.veritas.com/docs/DOC5332

- With SPC-2 SCSI reserve, devices may remain reserved after a failover in cluster environments or multi-path environments with failover capability.
 You cannot use SPC-2 SCSI reserve if the following factors are true: The failover does not break the device reservations and those devices that were in use during the failover must be available without manual intervention. Use SCSI persistent reserve.
- If the drive path changes, the backup jobs and the restore jobs fail.
 Therefore, jobs fail in cluster environments or any multi-path environments that share paths dynamically. If you cannot disable dynamic path sharing, you cannot use SPC-2 SCSI reserve or SCSI persistent reserve in NetBackup.

About SCSI reservation logging

The <code>bptm</code> process logs SCSI reservation-related commands. Examine the <code>bptm</code> log on all NetBackup media servers to ensure that the SCSI operations are logged. SCSI reservation commands are labeled SCSI PERSISTENT RESERVE or SCSI RESERVE in the log.

In addition, information about the SCSI persistent reservations that are broken are also written to the NetBackup Problems report.

About SCSI reserve operating system limitations on Windows

Windows operating systems cannot distinguish between a reserved device and a busy device. Therefore, PEND appears in the **NetBackup Administration Console Device Monitor** if another application controls the tape drive. NetBackup cannot share tape devices with other applications. If you use other applications, use the NetBackup tpreq command or Down the drive before using the drive.

These operating systems also may report PEND if the drive reports Busy when a volume is unmounted. Use the $AVRD_PEND_DELAY$ entry in the vm.conf configuration file to filter out these extraneous reports.

About checking for data loss

To detect data loss, the NetBackup bptm process reads the tape position and then verifies the actual position against the expected position.

If the actual position is less than the expected position at the end of the backup process, the following events occur:

- The tape is frozen.
- The backup fails.
- The following error message entry is written to the bptm log:

FREEZING media id xxxxxx, External event caused rewind during write, all data on media is lost

About possible data loss causes

If tape drive access protection is not enabled on the NetBackup media servers, the following may cause data loss: configuration errors, incorrect paths, multiple master servers, incorrect Shared Storage Option configurations, and third-party or operating system utilities.

If access protection is enabled on all NetBackup media servers, the following can cause data loss: any third-party or operating system utilities that run on the server that runs the NetBackup backup job.

Unfortunately, data loss cannot be prevented only recognized after the fact. NetBackup does not remove catalog information about the backup sessions that were lost. Use the <code>bpexpdate</code> command to expire the images for the lost backup sessions.

About checking for tape and driver configuration errors

To detect data loss, the bptm process reads the tape position and then verifies the actual position against the expected position.

If a configuration problem causes the actual position to be greater than the expected position at the end of the backup process, the following events occur:

- The tape is frozen.
- The backup fails.

The following error message entry is placed in the bptm log:

FREEZING media id xxxxxx, too many data blocks written, check tape/driver block size configuration

The backup data may be usable. If so, import the image by using the NetBackup bpimport command so the data is available for restores.

About common configuration problems

Identify and fix the source of the configuration problem that causes data loss. The most common configuration error is a failure to configure the driver for variable length blocks.

A less common error may be in the tape driver's configuration data, such as in the /kernel/drv/st.conf file on a Solaris system.

Information about tape driver configuration is available.

See the NetBackup Device Configuration Guide, available at the following URL:

http://www.veritas.com/docs/DOC5332

About configuring SCSI reserve

The SCSI reserve protection setting configures tape drive access protection for all tape drives from the media server on which the setting is configured. You can configure the protection for each media server and override the global setting for any drive path.

To configure SCSI reserve protection on a media server: use the **NetBackup Administration Console** to set the media server host property **Enable SCSI Reserve** on the **Media** tab.

To override the media server protection setting: use the **NetBackup Administration Console** to set the drive path property **Override SCSI reserve settings** when you add a drive or change a drive's properties.

How NetBackup selects media

How NetBackup selects media depends on whether the media is in a robot or a standalone drive.

See "About selecting media in robots" on page 184.

See "About selecting media in standalone drives" on page 186.

About selecting media in robots

When NetBackup receives a request for a volume, it searches the EMM database for the media ID. The external media ID should correspond to the NetBackup media ID.

A request for a volume includes the following attributes:

- The media ID
- The device density
- The file name that is used to link to the device that is assigned.

Table 5-9 describes the order in which NetBackup selects a volume in a robot.

 Table 5-9
 How NetBackup selects a volume in a robot

Order	Description
1.	NetBackup searches the media catalog for a volume that is already mounted in a drive and meets the following criteria:
	 Configured to contain backups at the retention level that the backup schedule requires. However, if the NetBackup Media host property Allow multiple retentions per media is specified for the server, NetBackup does not search by retention level. In the volume pool that the backup job requires. Not in a FULL, FROZEN, IMPORTED, or SUSPENDED state. Of the same density that the backup job requested, and in the robot that the backup job requested. Not currently in use by another backup or a restore. Not written in a protected format. NetBackup detects the tape format after the volume is mounted. If the
	volume is in a protected format, NetBackup unmounts the volume and resumes the search.
	If a suitable volume is found, NetBackup uses it.
2.	If NetBackup cannot find a mounted volume that satisfies all of the previous conditions, it checks the media catalog for any volume that is suitable.
	 If a suitable volume is in a robot, NetBackup issues the commands that move the volume to a drive, position the heads to the beginning of the volume, and assign it to the request. No manual intervention is required.
	 If a suitable volume is not in a robot but is in a standalone drive, NetBackup automatically mounts and assigns it. No manual intervention is required.
	 If a suitable volume is not in a robot or a standalone drive and the request is media-specific, NetBackup may pend a mount request. A media-specific mount request is one for a restore, for an import, or from the tpreq command.
	 If a suitable volume is not in a robot or a standalone drive, NetBackup may attempt to use another volume only as follows: For backup jobs for which any other media can be used.

Order	Description
3.	If a suitable volume does not exist or if a suitable volume is at end of media (EOM), NetBackup assigns a new volume. NetBackup may assign a new volume even if a volume is not full (because NetBackup received an EOM message from the drive).
	The new volume must meet all of the following criteria:
	 Is the correct media type
	 Is for the correct robot type (if applicable)
	 Is located in the requested robotic peripheral (if applicable)
	 Resides on the requested host
	 Is in the correct volume pool
	 Is not currently assigned (not already allocated to NetBackup)
	 Is not expired (if an expiration date is defined in NetBackup)
	 Has not exceeded the maximum number of mounts allowed
4.	If more than one volume qualifies, NetBackup chooses the volume that was least recently used.
	NetBackup then adds it to the media catalog and assigns it the specified retention level.
5.	If there are no unassigned volumes of the requested type, the backup terminates with an error message that no media were available.
	NetBackuptakes no action.

Table 5-9How NetBackup selects a volume in a robot (continued)

See "About spanning media with automatic media selection" on page 185.

About spanning media with automatic media selection

After an end of media (EOM) is reached, automatic media selection depends on whether NetBackup is configured to allow backups to span media, as follows:

 NetBackup spans media if the NetBackup Media host property Allow backups to span media is specified for the server.

In this case, NetBackup uses another volume to start the next fragment and the resulting backup is composed of fragments on different volumes.

 NetBackup does not span media if the media Allow backups to span media property is not specified.

In this case, the backup terminates abnormally and the operation is retried according to the NetBackup Global Attributes host property, **Schedule backup attempts**.

About selecting media in standalone drives

The following topics explain media selection and other aspects of standalone drive operations:

See "About selecting media by using standalone drive extensions" on page 186.

See "About disabling standalone drive extensions" on page 187.

See "About spanning media" on page 187.

See "About leaving standalone drives in the ready state" on page 188.

About selecting media by using standalone drive extensions

With NetBackup standalone drive extensions, NetBackup tries to use any labeled or any unlabeled media that is in a standalone drive. This capability is enabled by default during installation.

The media selection process is as follows:

- If a backup is requested and an appropriate standalone drive contains a volume, NetBackup tries to select and use that volume.
- If an appropriate drive does not contain a volume, NetBackup selects a volume. See "About selecting media in robots" on page 184. The Device Monitor shows the mount request, and an operator must manually insert the volume and assign it to a drive.

A volume that was used previously for backups must meet the following criteria:

- Not be FULL, FROZEN, or SUSPENDED
- Contain backups at the retention level and be in the same volume pool as the backup that requires a volume.
 However, if the NetBackup Media host property Allow multiple retentions per

media is specified for the server, NetBackup does not require a specific retention level.

NetBackup selects unlabeled media only if the existing volumes that meet the appropriate criteria do not have available space to contain the new backup images.

If the media is unlabeled, the following actions occur:

- NetBackup labels the media.
- NetBackup adds a media ID to the volume configuration, if necessary.
 If a media ID is added, the NetBackup Media ID prefix (non-robotic) is used as the first characters of the media ID.

- If a media ID prefix is not specified, the default prefix is the letter A. For example, A00000.
- NetBackup adds the requested volume pool to the volume configuration (if the backup policy specifies a volume pool).

If the unused media is unlabeled, label it by using the plabel command. Specify the -u parameter to force assignment of a specific drive index, which eliminates the need to assign the drive manually.

About disabling standalone drive extensions

Disable the standalone drive extensions by clearing the NetBackup media server host property, **Enable standalone drive extensions**. If this property is cleared, NetBackup uses the same method to select media for standalone drives as it uses for robotic drives.

About spanning media

Media selection after an end of media (EOM) condition depends on whether NetBackup is configured to allow backups to span media, as follows:

NetBackup spans media if the Allow backups to span media host property is specified for the server. NetBackup selects another volume to begin the next fragment, and the resulting backup has data fragments on more than one volume. After an EOM condition, NetBackup attempts to use an unassigned volume rather than one that already has images on it. NetBackup checks the EMM database for a volume that is the correct media type, in the correct volume pool, and so on.

If a suitable unassigned volume is unavailable, NetBackup selects a volume.

 NetBackup does not span media if the Allow backups to span media host property is not specified. The backup terminates abnormally when the end of media is reached. The operation is rescheduled according to the master server host property Schedule backup attempts.

You can further configure NetBackup behavior for standalone drives. Normally, when NetBackup spans media and an EOM is encountered on a standalone drive, NetBackup searches for other media or generates a pending mount request. You can configure a wait period for standalone drives. The wait period is helpful when a gravity feed tape stacker takes a long time to load the next media in the drive.

To configure NetBackup to wait, specify the **Media request delay** media server host property. This property specifies the number of seconds NetBackup waits to use a volume that is loaded in a compatible drive. After the wait period expires, NetBackup searches for another drive. NetBackup also waits to generate a pending mount request during tape span operations. The **Media request delay** property applies only when standalone drive extensions are enabled.

About leaving standalone drives in the ready state

To leave standalone drives in a ready condition after a backup or restore completes, use the nbemmcmd command to enable the -do_not_eject_standalone option. NetBackup does not eject the tape after an operation completes. The media is still ejected if EOM is reached or an error is encountered. Also, the media is ejected if the drive needs to be used with another media or the media needs to be used with another drive.

One standalone drive may be ready and contain suitable media.

Detailed information on the nbemmemd command is available.

See the NetBackup Commands Reference Guide, available at the following URL:

http://www.veritas.com/docs/DOC5332

Volume pool and volume group examples

The following three examples show the relationship between volume pools and volume groups.

See Figure 5-2 on page 189. for an example of one volume pool (named NB_pool) and several volume groups.

You can move volumes between the groups in the robotic library and any groups that are off site. All volumes, however, remain in the same pool.

Media in the same volume pools are in different volume groups. Note that the data is stored on separate volumes by assigning different volume pools. The volumes in a pool can be in more than one physical location and in more than one volume group.

			Standalone	
Rob	otic	NB_pool	Off-site 1	
Group 1	Group 2			
Group 3	Group 4			
			Off-site 2	
_				/
			! = !	

Figure 5-2Volume pool with multiple volume groups

See Figure 5-3 on page 190. for examples of how the volumes in the pool NB_pool_dept_1 are spread among the rob_A, standalone1, and off-site volume groups.

These groups also have volumes from more than one pool (though the volumes in each group must all be the same type). You also can configure a scratch pool from which NetBackup can transfer volumes when a volume pool has no media available.

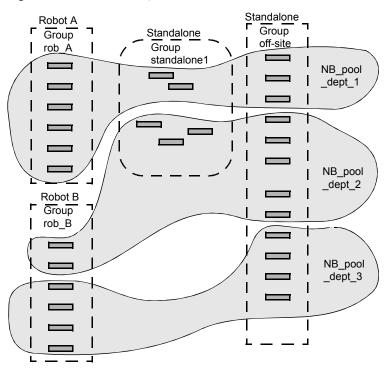

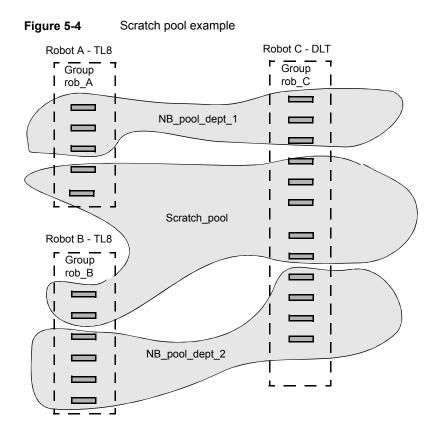

Figure 5-3 Volume groups with multiple volume pools

See Figure 5-4 on page 191. for an example where the scratch pool is named Scratch_pool. The three robots contain volumes from that pool in addition to those from other pools.

Assume the following sequence of events:

- A backup job requires a DLT volume, so NetBackup attempts to assign one from NB_pool_dept_1 in Robot C.
- Robot C has no unassigned volumes available in the NB_pool_dept_1 pool.
- NetBackup searches the scratch pool for an unassigned DLT volume in Robot
 C. If a volume is available, NetBackup moves it to NB_pool_dept_1. Otherwise,
 NetBackup logs a media unavailable status.

Media formats

NetBackup writes media in a format that allows the position to be verified before NetBackup appends new backups.

The following table shows the symbols that are used in the media format descriptions.

Table 5-10Media format symbols

Symbol	Description
MH	Media header (1024 bytes).
*	Tape mark.
BH	Backup header (1024 bytes).

Symbol	Description
BH1 BH <i>n</i>	Backup headers (1024 bytes). One for each job that is part of the set of the jobs that are multiplexed.
Image	Data from the backup.
EH	Empty backup header, which is used for position validation.

Table 5-10Media format symbols (continued)

The following table provides more information about how the media formats are used in different situations.

Format	Description
Standard tape format	For all tape media except quarter-inch cartridge (QIC) and WORM, the format for the backups that are not multiplexed is as follows:
	MH * BH Image * BH Image * BH Image * EH *
	When a new backup image is added, the tape is positioned to the EH and the position is verified. The EH is overwritten by a BH and the backup proceeds. When complete, a new EH is written for future position validation.
	When NetBackup encounters the end of media during a write operation, it terminates the tape with two tape marks and does not write an EH.
QIC and WORM tape format	This format is used for quarter-inch cartridge (QIC) and WORM media. Unlike the standard tape format, NetBackup does not write empty backup headers (EH). The format is as follows:
	MH * BH Image * BH Image * BH Image *
	To append backup images to QIC media, NetBackup positions to the end of data (EOD) and then starts the next backup.

 Table 5-11
 Media format descriptions

Format	Description
Fragmented backup format	For fragmented backups, the media format is similar to the standard tape format. The difference is that NetBackup breaks the backup image into fragments of the size that are specified when the storage unit is configured.
	The following is an example:
	MH * BH Image (frag 1)* BH Image (frag 2)* BH Image (frag n) * EH *
	Fragmentation is intended primarily for storing large backup images on a disk type storage unit.
	For multiplexed backups, image fragmentation results in faster restores because NetBackup can advance to the specific fragment before it begins a search for the file.
	Note: If an error occurs in a backup, the entire backup is discarded and the backup restarts from the beginning. It does not restart from the fragment where the error occurred. Exception: checkpoint and restart backups resume from the last checkpoint fragment.
Multiplexing format	The tape format for multiplexed backups is as follows:
	MH * BH1 BH <i>n</i> Image
	By default, the data image is in 64-kilobyte blocks. Each block also contains 512 bytes that are reserved for multiplexing control information and to identify the backup to which the block corresponds.
	When a job ends or a new job is added to the multiplexing set, NetBackup writes a tape mark. NetBackup then starts multiplexing the revised set of jobs.
	The following is an example:
	MH * BH1 BH2 BH3 Image* BH2 BH3 Image* BH2 BH3 BH4 Image
Spanning tape format	By default, NetBackup spans a backup image to another tape if it encounters the end of media during a backup. The format is the same as described for fragmented backups. The first fragment on the next tape begins with the buffer of data where the end of media occurred.
	The following is the first tape format (NetBackup does not write an EH and terminates the tape with two tape marks):
	MH * *BHn Image (frag 1) * *
	The following is the second tape format:
	MH * BHn Image (frag2)* * EH *

 Table 5-11
 Media format descriptions (continued)

Media and device management processes

Table 5-12 shows the NetBackup services and processes that control storage devices with removable media. NetBackup starts the processes as needed, but you can start some of them manually. The table also shows the commands that start each one.

These commands are located in the following directories:

UNIX	/usr/openv/volmgr/bin	
Windows	install path\VERITAS\Volmgr\bin	

For detailed information about the commands, see the *NetBackup Commands Reference Guide*, available at the following URL:

http://www.veritas.com/docs/DOC5332

	5
Command	Description
acsd	The Automated Cartridge System robotic process. The Device Manager ltid starts this process.
avrd	The Automatic Volume Recognition process. The Device Manager ltid starts this process.
ltid	Starts the NetBackup Device Manager service. Starting the Device Manager also starts the robotic, robotic control, Media Manager volume, and automatic volume recognition daemons.
	To stop the device, robotic, and robotic-control services, use the stopltid command.
tl4d	The tape library 4MM robotic process. The Device Manager ltid starts this process.
tl8cd	Starts the tape library 8MM robotic-control process. The Device Manager ltid starts this process.
t18d	The tape library 8MM robotic process. The Device Manager ltid starts this process.
	To stop the tape library 8MM robotic-control process, use <code>tl8cd -t</code> .
tldcd	Starts the tape library DLT robotic-control process. The Device Manager ltid starts this process.
	To stop the tape library DLT robotic-control process, use tldcd -t.

 Table 5-12
 Starting services and processes

Command	Description
tldd	The tape library DLT robotic process. The Device Manager ltid starts this process.
tlhcd	Starts the tape library Half-inch robotic-control process. The Device Manager ltid starts this process.
	To stop the tape library Half-inch robotic-control process, use tlhcd -t.
tlhd	The tape library Half-inch robotic process. The Device Manager ltid starts this process.
tlmd	The tape library Multimedia process. The Device Manager ltid starts this process.
vmd	The NetBackup Volume Manager service. The Device Manager ltid starts this process.

 Table 5-12
 Starting services and processes (continued)

On UNIX, you can use the kill *pid* command to stop the process for the daemon with the specified *pid* (process ID).

On Windows, you can start and stop services by using the **Services** tool available in **Administrative Tools** in the Microsoft Windows Control Panel. If they are started from the command line, some services occupy that NetBackup Console session until they are stopped.

For detailed information about most of the commands that are in the following tables, see the *NetBackup Commands Reference Guide*, available at the following URL:

http://www.veritas.com/docs/DOC5332

About Tape I/O commands on UNIX

To troubleshoot or test Media Manager, use the commands that are described in the following sections to manipulate volumes. Similarly, if you do not use NetBackup, you can use these commands to mount and manipulate volumes.

About requesting tapes

The tpreq command lets you request a tape of a particular density and specify various options, such as the access mode. This command reserves a single drive and creates a file in the current working directory (unless a full path is specified). The file acts as a symbolic link to the tape and all subsequent access to the tape

is through this file name. Users do not have to be concerned with the full path to a specific device file.

For all types of tapes, the tape is mounted and assigned when you enter the ${\tt tpreq}$ command.

By default, NetBackup assigns drives that support DLT cartridge tapes. You can use the density option on tpreq to request a drive that supports another density. For a list of supported densities and drive types, see the tpreq man page.

The density for the physical write is not selected automatically on drives. It's requested, so an operator can satisfy the correct drive. One of two methods is used to determine the drive density: the /dev device name that was used when the drive was configured or by how the drive is configured physically.

A tpreq command must include a media ID and a file name. If the tape volume is associated with a volume pool, the name of the volume pool can also be specified by using the -p parameter. If you specify the pool name, the name is validated against the pool name that is associated with the media in the EMM database.

The NetBackup tpreq command runs the drive_mount_notify script (if it exists) immediately after media is mounted in a pre-selected, robotic drive.

See "drive_mount_notify script (on UNIX)" on page 157.

See the NetBackup Commands Reference Guide, available at the following URL:

http://www.veritas.com/docs/DOC5332

About reading and writing tape files

Reading or writing tape files involves copying the file from tape to disk or from disk to tape. To perform read or write operations, use one of the UNIX commands that performs input and output operations, for example tar or mt.

Positioning tape files	The ${\tt mt}$ command positions tape files by skipping forward or backward according to tape marks.		
	The following options are available on the mt command for positioning tapes:		
	 eof, weof Writes an end-of-file tape mark at the current position on the tape according to the 		
	count option on mt.		
	 fsf, bsf Spaces forward or backward the number of tape marks on the count option. fsr, bsr 		
	Spaces forward and backward the number of records according to the count option on mt. bsr is only supported for the undefined record type.		
	The following example uses the ${\tt mt}$ command to skip forward three files on a tape:		
	mt -f tapel fsf 3		
Rewinding tape files	When a file is rewound, it is positioned to the beginning of the data. To rewind a tape file, you can use the $\tt mt$ command.		
	${\tt tapel}$ is positioned to the beginning of the tape volume that is associated with the file.		
	The following command rewinds file tape1:		
	mt -f tapel rewind		
	The count option is not used for the rewind operation. If you specify a count, $\tt mt$ ignores it.		

About removing tape files

When you have completed reading or writing tape files, use the /usr/openv/volmgr/bin/tpunmount command to end the assignment of the tape file. This command removes from the directory the tape file you created by with tpreq and removes the tape volume from the tape drive. The tpunmount command is required for each file that the tpreq command creates.

See the NetBackup Commands Reference Guide, available at the following URL:

http://www.veritas.com/docs/DOC5332

On UNIX, the NetBackup tpunmount command runs the drive_unmount_notify script (if it exists) after media is unmounted.

See "drive_unmount_notify script (on UNIX)" on page 157.
