Technical Support

Symantec Technical Support maintains support centers globally. Technical Support's primary role is to respond to specific queries about product features and functionality. The Technical Support group also creates content for our online Knowledge Base. The Technical Support group works collaboratively with the other functional areas within Symantec to answer your questions in a timely fashion. For example, the Technical Support group works with Product Engineering and Symantec Security Response to provide alerting services and virus definition updates.

Symantec's support offerings include the following:

- A range of support options that give you the flexibility to select the right amount of service for any size organization
- Telephone and/or Web-based support that provides rapid response and up-to-the-minute information
- Upgrade assurance that delivers software upgrades
- Global support purchased on a regional business hours or 24 hours a day, 7 days a week basis
- Premium service offerings that include Account Management Services

For information about Symantec's support offerings, you can visit our Web site at the following URL:

www.symantec.com/business/support/

All support services will be delivered in accordance with your support agreement and the then-current enterprise technical support policy.

Contacting Technical Support

Customers with a current support agreement may access Technical Support information at the following URL:

www.symantec.com/business/support/

Before contacting Technical Support, make sure you have satisfied the system requirements that are listed in your product documentation. Also, you should be at the computer on which the problem occurred, in case it is necessary to replicate the problem.

When you contact Technical Support, please have the following information available:

- Product release level

- Hardware information
- Available memory, disk space, and NIC information
- Operating system
- Version and patch level
- Network topology
- Router, gateway, and IP address information
- Problem description:
  - Error messages and log files
  - Troubleshooting that was performed before contacting Symantec
  - Recent software configuration changes and network changes

Licensing and registration

If your Symantec product requires registration or a license key, access our technical support Web page at the following URL:

www.symantec.com/business/support/

Customer service

Customer service information is available at the following URL:

www.symantec.com/business/support/

Customer Service is available to assist with non-technical questions, such as the following types of issues:

- Questions regarding product licensing or serialization
- Product registration updates, such as address or name changes
- General product information (features, language availability, local dealers)
- Latest information about product updates and upgrades
- Information about upgrade assurance and support contracts
- Information about the Symantec Buying Programs
- Advice about Symantec's technical support options
- Nontechnical presales questions
- Issues that are related to CD-ROMs or manuals

Support agreement resources

If you want to contact Symantec regarding an existing support agreement, please contact the support agreement administration team for your region as follows:

Asia-Pacific and Japan	customercare_apac@symantec.com
Europe, Middle-East, and Africa	semea@symantec.com
North America and Latin America	supportsolutions@symantec.com

About Symantec Connect

Symantec Connect is the peer-to-peer technical community site for Symantec's enterprise customers. Participants can connect and share information with other product users, including creating forum posts, articles, videos, downloads, blogs and suggesting ideas, as well as interact with Symantec product teams and Technical Support. Content is rated by the community, and members receive reward points for their contributions.

www.symantec.com/connect

Getting started with the CommandCentral family

This document includes the following topics:

- About the CommandCentral family
- About Veritas CommandCentral Storage
- About Veritas CommandCentral Storage Change Manager
- About Veritas CommandCentral Enterprise Reporter
- Getting CommandCentral up and running
- Where to find more information about CommandCentral

About the CommandCentral family

The CommandCentral family includes the following modules:

- CommandCentral Storage: A storage resource management solution that provides centralized visibility across heterogeneous storage environments while reducing risks and costs.
  For more information, refer to the following:
  See "About Veritas CommandCentral Storage" on page 8.

- CommandCentral Storage Change Manager: A storage change management solution that provides insight into storage infrastructure related changes in your data center, helping you to ensure the availability of your storage infrastructure, manage service level agreements more effectively, and improve operational efficiency.
  For more information, refer to the following:
  See "About Veritas CommandCentral Storage Change Manager" on page 12.

■ CommandCentral Enterprise Reporter: Provides a global view of storage assets mapped to your organization, business insight about inventory and utilization, on-demand customized reporting, and personalized dashboards.

For more information, refer to the following:

See "About Veritas CommandCentral Enterprise Reporter" on page 14.

About Veritas CommandCentral Storage

Veritas CommandCentral™ Storage by Symantec is a storage resource management (SRM) solution that helps you manage your storage infrastructure more effectively.

CommandCentral Storage includes the following capabilities:

■ Offers a single console that lets you visualize your networked storage environment through graphical and textual displays. The CommandCentral Storage Console seamlessly integrates performance and policy management to ensure that the storage infrastructure runs efficiently. The Console also lets you set the policies that automate notification, recovery, and other user-definable actions.

■ Discovers and tracks the utilization and allocation of storage resources down to the disk level. Reporting features provide a detailed view into how and where storage is used in your enterprise.

■ Shows the usage trends. Armed with this data, you can analyze the return on your storage investment. You also have what you need to implement a program of departmental chargeback.

Using CommandCentral Storage with other Symantec software, IT managers have tools to perform end-to-end storage resource management and make strategic decisions about future storage needs.

What you can do with CommandCentral Storage

CommandCentral Storage provides a single, centralized, consistent storage management console to simplify the complex tasks involved in deploying and growing a multi-vendor networked storage environment.

Symantec strives to help you manage the integrity of your information by enabling you to maintain the right balance of information security and availability. Symantec delivers market-leading technology, insight, and expertise in the areas of information security, data management, systems management, storage management, and application performance management.

With Symantec's unmatched breadth and depth, your IT organization can better align with business objectives and address the issues of cost, complexity and

compliance. Symantec is uniquely positioned to help keep your business up, running, and growing, no matter what happens.

Managing the storage network: introduction

Many organizations—as they adopt e-commerce, supply chain management, compliance, and other data-intensive applications—find that their data is exploding. More and more storage is needed to digitize manuals, corporate records, and other paper-based information, and to hold ever-increasing multimedia content.

If all that volume and complexity weren't enough of a management challenge, today's business environments demand that data be available immediately, continuously, and from anywhere—to multiple applications and to hundreds, thousands, or even millions of customers, business partners, and employees.

Storage network technologies

Historically, enterprises have relied heavily on parallel SCSI technology to provide the performance required for their enterprise data storage needs. More recently, however, some enterprises are finding that the restrictions imposed by SCSI architecture are too costly for SCSI to continue as a viable solution.

To overcome these restrictions, many enterprises have turned to a network-attached storage (NAS) model that enables storage arrays to reside directly on the main user network, where the access to storage is made through the server's network connection. However, this model can add a significant load to the network, which frequently is already starved for bandwidth.

Responding to this problem, some enterprises have implemented storage area networks (SANs) in which storage is placed on its own dedicated network. This dedicated network can improve efficiency and reliability by effectively separating traffic on the storage network from traffic on the main user network.

Storage virtualization

CommandCentral Storage is a valuable asset for enterprises that have implemented storage virtualization—the process of taking multiple physical storage devices and combining them into logical (virtual) storage devices that are allocated to applications and users at will.

Storage virtualization helps ease management by building a layer of abstraction above the physical storage; however, your administrators still need to penetrate that layer in order to view and manage the physical storage. CommandCentral Storage collects detailed information about how physical storage is apportioned and used, and it provides a graphical user interface for presenting the information to the administrator.

Although virtualization is not a new concept, CommandCentral Storage now enables you to take advantage of storage virtualization services over the entire storage network, across all types of storage hardware and server platforms. You also gain storage resource management capabilities such as hardware discovery, visualization, reporting, and a central administration point for your storage network.

Storage administrator requirements

Because both storage resources and IT personnel vary widely from enterprise to enterprise, the job of storage administrator is often filled by people with various skill sets and work backgrounds: mainframe operators, traditional network administrators, system administrators, and others in the IT industry.

In a utility computing environment, the storage administrator usually works closely with network administrators and others whose responsibilities range across the entire IT department. Nevertheless, the storage administrator needs to know details about how storage is apportioned and used on both the logical and physical levels. He or she is also responsible for providing overall guidance on how the storage network is used and on the direction it will take in the future.

Here are some examples of other tasks a storage administrator typically performs:

- Manage storage resources—for example allocating storage to hosts and the applications that run on them, and defining logical groups for easier management
- Test new vendors' hardware and integrate it into the storage network
- Generate reports about the network's physical resources and about storage usage
- Troubleshoot network elements
- Manage day-to-day performance and resource availability
- Develop a data protection strategy and assure that the storage network is secure

Meeting the needs of storage administrators with CommandCentral Storage

CommandCentral Storage can maximize the return on your investment in storage technology. It does so by providing tools designed to help the storage administrator optimize the operation of your storage network.

Discovery of storage resources

CommandCentral Storage contains in-band and out-of-band discovery methods for discovering a wide range of network or storage network objects. As a result, you can discover and monitor physical and virtual fabrics, hosts, groups, storage devices (such as arrays and NetApp unified storage devices), and applications. You can use the information that CommandCentral Storage discovers to identify the utilization and allocation of storage resources. For example, you can see how applications use storage.

Versatile displays of information about storage resources

The CommandCentral Storage Console provides a rich, versatile set of graphical and textual displays with which you can visualize physical resources—such as hosts and arrays—and logical resources—such as virtual fabrics—as well as the connections and interrelationships between them. Displays also include storage usage reports and projected storage consumption trends.

Policies for managing resources

Using the CommandCentral Storage Alert Manager, you can define and manage policies that are associated with objects in your storage network. A policy consists of a condition to monitor, such as heavy traffic on a specific switch port, and a set of actions to take when that condition is met. In addition to the policies you define, an extensive set of default policies is included with the CommandCentral Storage product.

Data collection to monitor the storage network

CommandCentral Storage includes a versatile set of collectors that gather information about network resources for evaluation by the Alert Manager. CommandCentral Storage collects information about capacity, environmental conditions (such as temperature), performance, traffic, errors, and object availability.

Graphical reports about network resources, performance, and events

CommandCentral Storage includes an extensive set of graphical reports with which you can display collected data about resources, performance, history, and changes on your storage network. You can also create custom reports tailored to your own needs. By enabling you to monitor things like trends in storage usage, these reports can help you use your storage assets more efficiently.

About Veritas CommandCentral Storage Change Manager

Veritas CommandCentral™ Storage Change Manager by Symantec provides enterprise–wide insight into storage infrastructure–related changes in your datacenter. With this insight, you can maximize storage availability and minimize downtime due to planned and unplanned changes.

CommandCentral Storage Change Manager includes the following capabilities:

■ Discovers the storage resources in your datacenter. This allows storage administrators to monitor your storage infrastructure.

■ Detects the changes made to your storage resources. This allows storage administrators to monitor changes and assess the impact those changes have on your storage infrastructure.

■ Assesses the changes to storage resources against custom policies and best-practice policies. With custom policies, storage administrators can define connectivity, configuration, and compliance requirements for your storage assets. Best-practice policies monitor your storage assets with industry–recognized best practices for storage management.

■ Notifies you of changes to storage resources that violate your custom policies. This allows storage administrators to correct the changes that can potentially disrupt your storage infrastructure.

■ Identifies potential risks to your storage infrastructure based on best-practice policies. With risks, storage administrators can identify the affected storage resources and take the necessary action to remove the risk from your storage infrastructure.

■ Lets you view reports that provide an enterprise–wide view of the changes that occur in your datacenter.

Use CommandCentral Storage Change Manager as your solution for storage change and configuration management to ensure the availability of your storage infrastructure, manage service level agreements more effectively, and improve operational efficiency.

What you can do with CommandCentral Storage Change Manager

Storage administrators can use CommandCentral Storage Change Manager to monitor and manage changes to the storage infrastructure. With CommandCentral Storage Change Manager, you can do the following:

- Monitor your storage resources and view detailed information about them. For example, you can view storage arrays and the LUNs that reside inside each array.

- Track changes to your storage resources. For example, you can view information about an application that was added to a host.

- Create custom policies. With custom policies, you can define the connectivity, configuration, and compliance requirements for your storage resources. Additionally, you can also define who should receive notifications of violations to the policy and you can define the target resolution time for violations.

- Monitor violations against your custom policies. When a violation occurs, you can view the violation to determine the impacted storage resources, find the change that caused the violation, and take the necessary actions to resolve the violation.

- Use best practice policies. These policies ship with CommandCentral Storage Change Manager and monitor storage changes against industry recognized best practices for storage management. For example, one best practice policy monitors clusters that host a service group to ensure that the cluster's nodes have access to the same set of LUNs.

- Monitor the risks that best practice policies identify. Similar to violations, CommandCentral Storage Change Manager generates a risk if a change breaches a best practice policy. You can view a description of each risk to identify impacted storage resources and then take the necessary action to resolve the risk.

- View reports that provide an enterprise–wide view of the changes made to your storage resources, a summary of the hosts and applications that have policies applied to them, and details about violations, including the time that it takes to resolve violations and the type of violations that have generated.

- Display an overall view of the current state of your data center. With the Dashboard, you can view graphs that detail the number of recent violations and changes. This allows you to identify current impacts and helps you to visualize storage change trends in your data center.

How CommandCentral Storage Change Manager works

CommandCentral Storage Change Manager can discover the storage resources in your data center. When changes occur to those resources, CommandCentral Storage Change Manager detects and aggregates the changes. During the detection process, CommandCentral Storage Change Manager assesses the changes against custom policies and best practice policies. If a change violates a custom policy, CommandCentral Storage Change Manager generates a violation. If a change

violates a best practice policy, CommandCentral Storage Change Manager generates a risk.

CommandCentral Storage Change Manager lets you interact with the storage objects it discovers, the changes it detects, and the violations it generates through its Console. You can also use the Console to manage custom policies and best practice policies, configure devices, view reports, and manage user accounts.

About Veritas CommandCentral Enterprise Reporter

Veritas CommandCentral Enterprise Reporter by Symantec (Enterprise Reporter) improves storage service management by aligning IT to business objectives. Enterprise Reporter offers business information executives and storage administrators the following:

■ Global views of storage assets mapped to your organization

■ Business insights into inventory utilization

■ On-demand customized reporting

■ Personalized dashboards for multiple users

Enterprise Reporter includes a central reporting interface for your storage infrastructure that unifies information from multiple data centers and organizes it along the lines of your business. If you are a business information executive, you can use Enterprise Reporter to view your storage environment at the enterprise level. You can then drill down into your organization's hierarchy, which could be organized by location, departments, or any other logical business unit. This summarized information enables you to assess trends in your storage environment, which you can then analyze to assign responsibility.

If you are a storage administrator, you can use Enterprise Reporter to identify capacity trends, review storage inventory, and determine your storage costs per business unit. With this information, you can promote storage accountability and decrease costs.

Figure 1-1   Report types and scopes

Use Enterprise Reporter to answer questions like the following:

■ Which applications are growing out of control?

■ What will my tier 1 storage growth look like next year?

■ How is capacity trending in North America versus Europe?

■ How is storage allocated in the finance department?

■ Which department uses the highest percentage of tier 1 storage in the Toronto data center?

Storage administrators and business users operate Enterprise Reporter with CommandCentral Storage. While CommandCentral Storage provides storage reporting for a single data center and is used at an operational level, Enterprise Reporter lets you aggregate storage information from multiple data centers and view storage assets by a variety of business dimensions. For example, if you are a business information executive, you could use Enterprise Reporter to identify the trend of unclaimed tier 1 storage in your New York and Zurich data centers. You could then ask the storage administrators at each site to use CommandCentral Storage to drill down to the details of which arrays or LUNs are unclaimed.

What you can do with CommandCentral Enterprise Reporter

Enterprise Reporter includes a global view of storage with the ability to roll up information from multiple data centers into a single comprehensive view – organized by lines of business, geography, application, or other customized views. It can help you compare trends across continents, find the application consuming the most storage in a particular data center, or locate the business unit consuming more than its fair share of storage.

Storage administrators can use Enterprise Reporter along with CommandCentral Storage. While CommandCentral Storage provides an operational view of storage

data primarily for storage administrators, Enterprise Reporter summarizes this data across data centers and integrates business information, giving CIOs, directors, and business unit leaders a more global view.

For example, business leaders use Enterprise Reporter to identify storage trends (such as an alarming regional growth rate of tier 1 storage). Then, administrators use CommandCentral Storage to help ensure that the appropriate storage service is being delivered to the business.

Business executives and storage administrators can use Enterprise Reporter to do the following:

- Develop highly customizable business views of data from multiple data sources. For example, administrators can discover global storage usage trends and drill down to identify high consumers across geographic or business units.

- Create storage tiers that match business needs and associate costs with each tier. Administrators can then identify where storage is allocated appropriately to costly tiers.

- Create ad hoc reports quickly by inserting data fields (such as host attributes, array attributes, allocated capacity, and claimed capacity) into a report table. Add selectable and customizable filters to narrow the focus or display data visually using charts for quick interpretation. To focus on specific business units, users can drag customized business view options into the report, easily grouping data into business units.

- Create advanced reports incorporating more advanced layout options, such as maps, images, and HTML. Also, add multiple queries to reports or insert prompts that request report users to select the report focus that they want before running the report.

- Generate reports automatically with a specified schedule and set automated distribution through email.

- Develop a personalized dashboard in Cognos Connection containing customized reports that display answers you need quickly.

- Select a sample report or report you created as the default report for the Enterprise Reporter Dashboard.

How CommandCentral Enterprise Reporter works

Multiple data centers, each with one or more CommandCentral Storage Management Servers, send data to Kettle, which performs extract, transform, and load (ETL) processes. Kettle aggregates the data and prepares it for use by the Oracle database. Kettle then loads the data into the Oracle database.

The Oracle database, an enterprise-scalable database, stores the data and passes it to Cognos. Cognos enables users to select data, filters, and business views to develop customized reports. Administrators and analysts use Cognos Connection, Query Studio, and Report Studio to create personalized dashboards and design reports.

Enterprise Reporter lets users see the aggregated data in customizable reports via its Console. Administrators also use the Console to configure data rollup, storage tiers, business views, and user accounts.

Getting CommandCentral up and running

To get CommandCentral up and running, review information about planning tips, system requirements, and the installation process. The following topics provide more information:

- See "Planning tips for installation, configuration, and deployment of CommandCentral" on page 17.

- See "System requirements for CommandCentral" on page 17.

- See "Installation overview" on page 19.

Planning tips for installation, configuration, and deployment of CommandCentral

To plan your installation of the CommandCentral modules, do the following:

- Select the hosts on which you will install CommandCentral components

- Configure network devices for discovery and management

- Prepare your Oracle database (Enterprise Reporter only)

- Consider how you will implement the Symantec Product Authentication Service

Review a complete set of planning considerations in the following documents:

- For CommandCentral Storage and CommandCentral Storage Change Manager, refer to the *CommandCentral Installation Guide*.

- For Enterprise Reporter, refer to the *CommandCentral Enterprise Reporter Installation Guide*.

System requirements for CommandCentral

To help plan your installation, review information about operating system requirements and Web browser support.

Supported operating systems for CommandCentral

The CommandCentral modules are supported in a variety of popular operating environments.

Table 1-1 identifies the supported operating systems for CommandCentral components.

Table 1-1   Supported operating systems for CommandCentral components

Component	Operating systems supported
CommandCentral Storage Management Server	Solaris and Windows
CommandCentral Storage Change Manager Management Server	Solaris and Windows
Enterprise Reporter Management Server	Solaris and Windows
CommandCentral Control Host	Solaris and Windows
CommandCentral Standard Agent	Solaris, Windows, Red Hat Linux, SUSE Linux, AIX, and HP-UX
Unified Agent	Solaris, Windows, Red Hat Linux, SUSE Linux, AIX, and HP-UX

For information about which versions of each operating system is supported, refer to the following:

■ *CommandCentral Storage Release Notes*

■ *CommandCentral Storage Change Manager Release Notes*

■ *CommandCentral Enterprise Reporter Release Notes*

Web browser support for the CommandCentral Console

You can log in to the CommandCentral Console using the following Web browsers:

■ Microsoft Internet Explorer (Windows only)

■ Mozilla (Solaris only)

■ Mozilla Firefox (Windows only)

For information about which versions of each browser is supported, refer to the following:

- *CommandCentral Storage Release Notes*

- *CommandCentral Storage Change Manager Release Notes*

- *CommandCentral Enterprise Reporter Release Notes*

Installation overview

To install CommandCentral, you need to do the following:

- Review installation prerequisites

- Mount the product disc

- Run the product installer

- Perform post-installation setup

For more information about the installation process refer to the following:

- For CommandCentral Storage and CommandCentral Storage Change Manager, refer to the *CommandCentral Installation Guide*.

- For CommandCentral Enterprise Reporter, refer to the *CommandCentral Enterprise Reporter Installation Guide*.

Where to find more information about CommandCentral

Use the following topics to find more information about CommandCentral:

- See "CommandCentral on the Web" on page 19.

- See "About Symantec Operations Readiness Tools" on page 20.

- See "Getting help" on page 21.

- See "About CommandCentral documentation" on page 21.

- See "Commenting on product documentation" on page 24.

CommandCentral on the Web

For comprehensive, up-to-date information about CommandCentral, visit the Symantec Web site:

www.symantec.com/business/products/family.jsp?familyid=commandcentral

About Symantec Operations Readiness Tools

Symantec™ Operations Readiness Tools (SORT) is a set of Web-based tools and services that lets you proactively manage your Symantec enterprise products. SORT automates and simplifies administration tasks, so you can manage your data center operations more efficiency and get the most of out of your Symantec products.

SORT lets you do the following:

- Collect, analyze, and report on server configurations across UNIX or Windows environments. You can use this data to do the following:

    - Assess whether your systems are ready to install or upgrade Symantec enterprise products

    - Tune environmental parameters so you can increase performance, availability, and use

    - Analyze your current deployment and identify the Symantec products and licenses you are using

- Upload configuration data to the SORT Web site, so you can share information with coworkers, managers, and Symantec Technical Support

- Compare your configurations to one other or to a standard build, so you can determine if a configuration has "drifted"

- Search for and download the latest product patches

- Get notifications about the latest updates for:

    - Patches

    - Hardware Compatibility Lists (HCLs)

    - Array Support Libraries (ASLs)

    - Array Policy Modules (APMs)

    - VCS agents

- Determine whether your Symantec enterprise product configurations conform to best practices

- Search and browse the latest product documentation

- Look up error code descriptions and solutions

To access SORT, go to:

http://sort.symantec.com

Getting help

If an issue arises while you are using CommandCentral, use the following information to pinpoint the problem and, if necessary, report it to Symantec.

For technical assistance, visit the following Web site:

http://www.symantec.com/enterprise/support/assistance_care.jsp

and select phone or email support. This site also provides access to resources such as TechNotes, product alerts, software downloads, hardware compatibility lists, and the Symantec customer email notification service. Use the Knowledge Base Search feature to access additional product information, including current and past releases of product documentation.

For license information, software updates and sales contacts, visit the following Web site:

https://licensing.symantec.com

About CommandCentral documentation

For information about CommandCentral product documentation, refer to the following:

- See "About CommandCentral Storage documentation" on page 21.

- See "About CommandCentral Storage Change Manager documentation" on page 22.

- See "About CommandCentral Enterprise Reporter documentation" on page 23.

About CommandCentral Storage documentation

You can access CommandCentral Storage documentation at the Symantec Technical Support Web site:

http://www.symantec.com/enterprise/support/documentation.jsp?pid=50379

Table 1-2 describes the CommandCentral Storage documentation.

Table 1-2   CommandCentral Storage documentation

Guide	Description
CommandCentral Administrator's Guide	Provides information about how to administer the product. For example, the guide describes how to manage licenses and user accounts, configure product components, and work with diagnostic information.

Table 1-2 CommandCentral Storage documentation *(continued)*

Guide	Description
CommandCentral Getting Started Guide	Provides a high-level overview of how you can use CommandCentral Storage.
CommandCentral Hardware and Software Configuration Guide	Provides setup requirements for applications and devices and instructs you how to configure CommandCentral Storage to discover them.
CommandCentral Hardware and Software Compatibility List	Lists the devices and applications that CommandCentral Storage supports.
CommandCentral Installation Guide	Instructs you how to install CommandCentral Storage.
CommandCentral Storage Release Notes	Provides information about supported operating systems, host resource requirements, software limitations, and known issues.
CommandCentral Storage User's Guide	Describes how you can use CommandCentral Storage to monitor, manage, and report on your storage infrastructure.
CommandCentral Third-Party License Agreements	Provides information about third-party software that is used in CommandCentral Storage and CommandCentral Storage Change Manager.

About CommandCentral Storage Change Manager documentation

You can access CommandCentral Storage Change Manager documentation at the Symantec Technical Support Web site:

www.symantec.com/enterprise/support/documentation.jsp?pid=54974

Commenting on product documentation

Submit comments about the product documentation to the following email address:

storage_management_docs@symantec.com

Please include the following information with your documentation comments:

- The title and product version of the guide you are commenting on
- The topic (if relevant) you are commenting on
- Your comment
- Your name

Glossary

access group	See array virtual port.
active zone set	The zone set that is currently enforced on a Fibre Channel fabric. Only one zone set can be active for a fabric at a given time. See also zone set.
addressable storage	See LUN storage.
addressable unit	Any storage resource in the network that is ready to be allocated for use by hosts and applications. Also called AddrUnit or AU. See also LUN.
Agent	See Standard Agent and Unified Agent.
agentless	The ability to discover information about a host without installing an agent on the host. Agentless capabilities provide two ways to discover host information. The first way is the ability to discover basic information about a host by associating HBAs to user-created hosts. The second way is the ability to discover detailed information about a host by remotely running agentless discovery scripts on the host.
agentless host	A host that CommandCentral Storage discovers by remotely running scripts that discover information about the host. See also agentless.
aggregate	A manageable unit of RAID-protected storage in a NetApp unified storage device, consisting of one or two plexes and containing one traditional volume or multiple FlexVol volumes. See also volume.
Alarm Service	See CommandCentral Storage Alarm Service.
alert	One of several types of configurable notifications produced when a CommandCentral Storage Alert Manager alarm is triggered. Every alert in CommandCentral Storage is dynamic, resetting itself automatically when a condition monitored by a policy returns to its specified CLEAR state.
Alert Manager	See CommandCentral Storage Alert Manager
allocated storage	The total amount of addressable storage in LUNs that is designated for use by specific hosts. A LUN is considered allocated when a host operating system has written a device handle for the LUN (in other words, claimed the LUN) or when the array has masked the LUN to a specific target. Contrast with unallocated storage.
application	A program or group of programs designed to perform a specific task. Oracle Database and Veritas NetBackup are examples of applications.

arbitrated loop	A topology for Fibre Channel networks in which nodes are connected in a single logical loop or ring created by tying the transmit lead of one node loop port to the receive lead of its downstream neighbor. There are primarily two types of arbitrated loops—public loops and private loops. A public loop is attached to a SAN fabric. A private loop is a free-standing arbitrated loop with no SAN attachment.
array	See storage array.
array host group	See array virtual port.
array virtual port	A logical—or, as it is commonly called, "virtual"—port defined for some array types that support SMI-S 1.0.2 and earlier. When an array virtual port (or AVP) is defined, the array can support LUN masking with multiple, heterogeneous hosts through a single physical array port. Depending on the array vendor, array virtual ports may also be known as host storage domains, array host groups, access groups, and affinity groups. See also storage view.
attribute	A property of an object that describes something about the object—such as its World Wide Name. The number and kind of attributes displayed for a resource depend on what type of object it is.
Audit Log	A text file that contains a list of all changes made to the Hardware Abstraction Layer—such as devices added and removed—and to the CommandCentral Storage Alert Manager—such as modifications to policy and alert notification and changes to configuration settings.
Authentication Service	See Symantec Product Authentication Service.
Authorization Service	See Symantec Product Authorization Service.
available storage	Configured storage that has not yet been apportioned into addressable units (LUNs). This storage is typically part of RAID groups. Contrast with LUN storage.
BCV (business continuance volume)	An area of virtual storage that maps to a LUN on an EMC Symmetrix or DMX array and provides redundancy. Each BCV contains a copy of a standard device (STD).
bind	The act of associating one or more thin devices with a thin pool.
binding	See LUN binding.
bridge	A device that connects and passes packets between two segments of a storage network that use the same communications protocol. See also router.
broadcast address	An IP address specified for discovering hosts running the Hardware Abstraction Layer within a subnet. 255.255.255.255 is a special IP address that CommandCentral Storage can use to search for hosts within a subnet without crossing a subnet boundary.

bundle	A logical grouping consisting of up to 16 physical links. CommandCentral Storage can discover, act upon, and display information about a bundle as if it were a single link. Also called port bundle.
capacity	The amount of storage an object can allocate or use.
ccconfig	See Command Central Configuration Utility.
circuit breaker	A function in the CommandCentral Alert Manager that automatically limits the number of notifications sent to a recipient within a specified time.
claimed storage	Storage for which at least one host's operating system has created a device handle. Contrast with unclaimed storage.
CLARiiON storage group	In an EMC CLARiiON storage array, a set of addressable units (LUNs) defined so that an operator can perform one LUN masking operation for the entire set of LUNs rather than separately for each LUN. Contrast with storage group.
cluster	A set of hosts (each termed a node) that share a set of disks and are connected by a set of redundant heartbeat networks.
cluster communication	Communication between clusters using either of the two core communication protocols defined by Veritas Cluster Server: GAB and LLT. The communication takes place by means of heartbeat signals sent between systems or fast kernel-to-kernel broadcasts.
collector	A measurement representing a specific state or numerical value for objects in the storage network. The Alarm Service uses collectors to monitor and correlate status and performance information, using several different processes. The Alert Manager uses information gathered by collectors to trigger policy actions such as SMTP mail, console alerts, commands, and logging. See also policy.
CommandCentral Storage	A product offering designed to maximize the return on an enterprise's storage technology investment by providing tools with which a storage administrator can make the storage network or SAN operate as effectively as possible.
CommandCentral Storage Agent Push Install Utility	A Windows-based utility with which you can install a Standard Agent that enables the collection of data through a variety of explorers. Using the Agent Push Install Utility, you can manage installs, upgrades, and uninstalls for multiple Windows-based Standard Agents from one central location.
CommandCentral Storage Alarm Service	A Server component (Windows service/UNIX daemon) that retrieves and correlates SNMP and other data and sends alerts to the CommandCentral Storage Alert Manager for further processing using defined policies. The Alarm Service has a command-line interface—`vxascmd`—with which you can connect to an Alarm Service server to obtain server and object information and perform various Alarm Service commands and queries.
CommandCentral Storage Alert Manager	A Server component that manages policies associated with objects on the storage network. A policy associates certain sets of conditions with storage resources and

defines actions to be taken when these conditions are detected. The Alert Manager is seamlessly integrated with the CommandCentral Storage product so that Console users can monitor, define, and modify policies.

CommandCentral Storage Console
A graphical user interface that displays reports and other information for users of the CommandCentral Storage product through a standard Web browser. The Console provides a central point to display and manage storage resources, create and modify policies, provision storage, administer access control, and view reports.

CommandCentral Storage database
A database, residing on the Management Server, that gathers data related to performance and monitoring, reports, alarms, service requests, and the Hardware Abstraction Layer (HAL). A Sybase ASA (Adaptive Server Anywhere) database management system, the database is installed silently when you install CommandCentral Storage.

CommandCentral Storage Management Server
The portion of the CommandCentral Storage product offering that resides on the primary host. It contains components such as the primary Hardware Abstraction Layer, CommandCentral Storage database, web engine, and Alert Manager, and Alarm Service.

CommandCentral Storage Web Engine
The software component that supplies the data seen by users of CommandCentral Storage. The Web Engine receives data from one or more Servers and delivers the data to users through a standard Web browser.

configured storage
Physical storage that has been formatted and is ready to be apportioned into RAID groups. Contrast with unconfigured storage.

Console
See CommandCentral Storage Console.

Control Host
The Control Host is a CommandCentral Storage component that includes the same capabilities as the Standard Agent. However, it also lets you discover arrays, switches, VMware ESX servers, and remote hosts through agentless discovery.

consumed capacity
The actual amount of storage in use for the thin device.

data device
An internal device that provides the storage capacity that thin devices use.

data device extent
The minimum amount of storage that is allocated at a time when you dedicate a data device from a thin pool for use with a specific thin device.

data store
See CommandCentral Storage database.

delete
In CommandCentral Storage, an operation that removes discovery information about one or more objects from the CommandCentral Storage database. The states of the objects themselves—for example, the existence of a LUN on an array or the configuration of a switch—are not affected by the delete operation. Optionally, deleted information can be restored to the database by a rediscover operation. Contrast with destroy. See also rediscover.

destroy	In CommandCentral Storage, an operation that modifies the configuration of one or more devices in the SAN. Examples are destroying zones and destroying port bundles, both of which modify the configuration of one or more switches. Unlike deleted objects, destroyed objects cannot be restored to the CommandCentral Storage database by a rediscover operation. Contrast with delete.
device	A collective term for disks, tapes, disk arrays, tape arrays, and any other objects that store data. Also storage device.
device handle	The name the operating system uses to identify a storage resource (known as an addressable unit or LUN), and the correct means (driver, system call) to access it. Also OS handle.
disabled data device	See unusable data device.
discovery	The process of finding objects on the storage network and adding information about them to a database. In CommandCentral Storage, most discovery is done by the Hardware Abstraction Layer, which stores information about storage resources in the CommandCentral Storage database. Discovery of storage arrays is performed by the Veritas Array Integration Layer (VAIL). See also explorer and extended discovery.
discovery data store	In CommandCentral Storage version 4.x, the cached database containing the names and attributes of all objects discovered and maintained by the SAN Access Layer (SAL). In version 5.x, the discovery data store no longer exists. Discovery data is stored in the CommandCentral Storage database.
disk array	A collection of disks controlled and managed through firmware. See also storage array.
disk device	A rewriteable, randomly addressable data storage device.
disk group	A collection of disks that share a common configuration. A disk group configuration is a set of records containing detailed information on existing Veritas Volume Manager objects (such as disk and volume attributes) and their relationships. Each disk group has an administrator-assigned name and an internally defined unique ID. The root disk group (rootdg) is a special private disk group that always exists.
DMP (Dynamic Multipathing)	A feature of Veritas Volume Manager that provides greater reliability and better performance by using path failover and load balancing for multiported disk arrays connected to host systems through multiple paths. DMP detects the various paths to a disk using a mechanism that is specific to each supported array type. DMP can also differentiate between different enclosures of a supported array type that are connected to the same host system.
enabled data device	See usable data device.

enclosure	In CommandCentral Storage, a method for visually grouping objects in the Console's Managing Summary pane or Topology Map. For example, a user might choose to represent a JBOD visually as an enclosure instead of as one or more separate disks.
event	A notification that indicates when an action, such as an alert or a change in state, has occurred for one or more objects on the storage network.
explorer	A software tool that uses a unique methodology to discover information about a particular kind of resource on the storage network. The CommandCentral Storage product includes several explorers that are used to locate resources and discover information about them. See also discovery.
extended discovery	A CommandCentral Storage feature that enables discovery of all LUNs and Fibre Channel ports in a storage device along with additional LUN attributes. Extended discovery is activated when you install the product with the array management feature. See also discovery.
extent	A continuous space on a disk or storage volume that is occupied by or reserved for a particular data set, data space, or file.
extent mapping	Specifies the relationship between a thin device and data device extents. The extent sizes between a thin device and a data device do not need to match.
extent pool	In an IBM DS6000 or DS8000 array, a storage virtualization object that aggregates the extents from a set of ranks. See also extent rank.
fabric	A group of SAN objects connected by a Fibre Channel (FC) switch. A fabric contains at least one FC switch and may also contain zones.
failover	A backup operation that automatically switches to a standby database, server, or network if the primary system fails or is temporarily shut down for servicing.
FC-GS-3	Fibre Channel third-generation generic services. An ANSI (American National Standards Institute) standard that defines commonly-used Fibre Channel services such as the name server, management server, and time server. In CommandCentral Storage, this standard is used for the GS explorer to discover Brocade switches. See also Fibre Channel GS explorer.
Fibre Channel	A collective name for the fibre optic technology that is commonly used to set up a storage area network (SAN) or virtual fabric (VSAN). A set of standards capable of transferring data between ports and through network devices at higher speeds and over significantly greater distances than SCSI technology, Fibre Channel supports point-to-point, loop, and fabric topologies.
file system	A means of organizing the addressable (LUN) storage of one or more physical or virtual disks to give users and applications a convenient way of organizing files. File systems appear to users and applications as directories arranged in a hierarchy.

filter	In CommandCentral Storage, a feature in tables and in the Topology Map with which a user can limit the number and types of objects displayed. Also, a way in which an administrator can limit the amount of data collected by the Exchange explorer during an Exchange scan.
firmware	A set of software instructions set permanently in a device's memory.
GBIC	Gigabit interface converter. A widely used transceiver module for Fibre Channel. A GBIC is modular and hot-swappable and can be either copper or optical.
generic device	A disk or tape device. When generic storage devices are visible to a host running the Hardware Abstraction Layer (HAL), the CommandCentral Storage Console displays the correct object type.
generic group	A user-defined collection of switches, hosts, and storage devices. The Group Builder tool is used to create and modify generic groups. See also group, object dependency group.
group	A class or collection of storage objects. Groups are useful for a number of different purposes, for example scoping reports and views to encompass a set of objects with similar attributes. CommandCentral Storage supports two types of groups: generic groups, which are defined by users, and object dependency groups, which are defined automatically to track volumes and file systems having dependencies on specific applications.
GS explorer	An explorer that uses the Fibre Channel Common Transport (CT) protocol to discover switches in-band over Fibre Channel, obtain switch characteristics, and explore port connectivity. Prior to CommandCentral Storage version 5.x, the GS explorer was known as the MGEX explorer.
guest operating system	An operating system that is installed on a virtual machine. See also managed virtual host.
HAL (hardware abstraction layer)	A component that performs device discovery and management for storage applications and devices. HAL maintains a real-time topology of the storage network and interacts directly with switches and storage arrays to control access to storage resources. HAL extends the functionality offered in previous releases of CommandCentral Storage, providing the ability to monitor and manage a large number of storage devices.
hard zoning	A fabric zoning method in which a Fibre Channel switch actively blocks access to zone members from any objects outside the zone. Because the active blocking takes place at the level of ports on the switch, hard zoning is also referred to as switch port zoning. In hard zoning, each switch uses a routing table to determine whether data is allowed to flow across a connection. See also soft zoning
HBA	Host bus adapter. An interface between a server or workstation bus and a Fibre Channel network.

HBA port group	A group of HBA ports for which a single LUN masking operation applies to each port in the group. In CommandCentral Storage, you can create HBA port groups using the Console. For HP EVA and EMC CLARiiON arrays, the term host may be used to refer to an HBA port group. For NetApp devices, the term initiator group is used. See also LUN masking.
host bus adapter	See HBA.
host storage domain	See array virtual port.
hub	A common connection point for devices in the storage network. The hub may be unmanaged, IP-managed, or FC-managed. An unmanaged hub is passive in the sense that it serves simply as a conduit for data, moving the data from one storage resource to another. IP-managed and FC-managed hubs are intelligent, containing features an administrator can use to monitor the traffic passing through the hub and configure each port in the hub.
inactive zone set	A zone set available for activating on a Fibre Channel fabric. See also active zone set, zone set.
in-band	A type of Fibre Channel management protocol. The most prevalent in-band protocol over Fibre Channel is SCSI Enclosure Services (SES). Contrast with out-of-band.
incremental threshold	A user-defined consumed capacity percentage that triggers an alert when consumption increases by a particular amount.
initiator group	See HBA port group.
IP address	An identifier for a computer or other device on a TCP/IP network, written as four eight-bit numbers separated by periods. Messages and other data are routed on the network according to their destination IP addresses. See also virtual IP address.
iSCSI router	A storage router implementing the Internet Small Computer Systems Interface (iSCSI) protocol (SCSI over IP) to extend access of a Fibre Channel fabric and attached storage devices to IP servers. Currently, CommandCentral Storage discovers only the Cisco SN 5420 iSCSI router.
JBOD (just a bunch of disks)	A cabinet of disks.
logical unit number	See LUN.
logical volume	A simple volume that resides on an extended partition on a basic disk and is limited to the space within the extended partitions. A logical volume can be formatted and assigned a drive letter, and it can be subdivided into logical drives. See also LUN.
LUN (logical unit number)	A unique and discrete addressable unit or logical volume that may reside inside one or more simple or array storage devices. LUNs are exposed to the outside

world through an addressing scheme presented to the host as SCSI LUN numbers. Each LUN has a unique device handle and represents a logical volume.

LUN binding	The creation of access paths between an addressable unit (AddrUnit) within a disk array and a port on the array. AddrUnits are storage volumes built out of the physical disks within the array. Array ports are connected to the SAN fabric and function as SCSI targets behind which the AddrUnits bound to those ports are visible.
LUN masking	The practice of enabling access to a particular addressable unit (AddrUnit) for a host on the storage network. This is done by creating an access control list associated with the LUN (the access path) between that AddrUnit and an array port to which it is bound. The access control list for a LUN contains the World Wide Name of each HBA port that is allowed to access that LUN within the array.
LUN Query Tool	A CommandCentral Storage tool that helps you find LUNs on your storage network that match one or more properties, such as device vendor, storage type, capacity, configuration, cost, and location. The LUN Query Tool can further refine the search for LUNs based on the groups to which they are assigned or based on their accessibility from specified SAN-attached hosts.
LUN storage	Configured storage that has been apportioned into addressable units (LUNs) and is ready to be allocated to hosts. Also called addressable storage. Contrast with available storage.
managed host	See Standard Agent.
masking	See LUN masking.
metadata space	See overhead.
MGEX	See GS explorer.
mirroring	A form of storage redundancy in which two or more identical copies of data are maintained on separate volumes. (Each duplicate copy is known as a mirror.) Also RAID Level 1.
multipathing	Multiple physical access paths to a disk connected to a host system. Any software residing on the host (for example, the DMP driver) that hides multiple physical access paths from the user is said to provide multipathing functionality. See also Dynamic Multipathing (DMP).
NetApp unified storage	A class of storage devices in which hosts and users gain access to storage through a specialized set of protocols. The NetApp unified storage system handles both SAN and NAS transactions and makes the specifics of each networked storage model (Fibre Channel SAN, iSCSI SAN, and NAS) transparent to the user.
NetBackup	See Veritas NetBackup.

node	An object in a network. In Veritas Cluster Server, node refers specifically to one of any number of hosts in a cluster. See also object.
object	A single, unique addressable entity on a storage network. It is possible for objects to be present within objects. For example, while a tape array is an object, each individual tape drive within the array is also an object. A host is an object, and the HBA inside the host is also an object. Each object has one or more attributes and can be a member of one or more zones.
object dependency group	A class or collection of storage objects, such as volumes and file systems, having dependencies on a specific application. Object dependency groups are defined automatically in CommandCentral Storage. See also generic group, group.
OID (object ID)	A key which uniquely identifies a discovered object in the CommandCentral Storage database. OIDs are represented in XML files as hexadecimal strings with a maximum length of 128 characters. Also called object reference.
object view	A graphical display showing storage resources and information about them.
OS handle	See device handle.
out-of-band	A type of communication protocol other than the Fibre Channel management protocol, such as SNMP or a vendor-specific proprietary protocol. Contrast with in-band.
overhead	Storage space that an array uses to perform bookkeeping operations for the thin provisioning configuration.
oversubscribed	A state in which the thin device capacity exceeds a thin pool's available storage capacity. Oversubscription allows the server to view more than the amount of storage capacity that is reserved on the storage array.
path	The route through which a host accesses data on a storage medium such as a disk in an array. The path consists of an HBA (host bus adapter) on the host, a SCSI or Fibre Channel connector, and a controller on the disk or disk array.
physical fabric	The physical components of a fabric, including all switches and all other SAN objects. You can configure one or more virtual fabrics—each one isolated from the others—based on the hardware components in the physical fabric.
policy	A set of rules, or configuration settings, that are applied across a number of objects in the storage network. You establish policies to help you monitor and manage the network. Each policy associates certain sets of conditions with storage resources and defines actions to be taken when these conditions are detected. See also collector.
Policy Service	See CommandCentral Storage Alert Manager.
port	A connection through which a device is attached to an I/O bus or to the storage network, or the representation of this physical connection to the link hardware.

port bundle	See bundle.
primary server	See server.
provisioning	The set of activities by which a user allocates storage to hosts and applications, for example creating LUNs in an array, setting up zoning between a host and an array, and giving the server access to the storage. CommandCentral Storage provides a set of tools, such as the LUN Masking wizard and the Zone Builder, that assist the provisioning process.
Push Install	See CommandCentral Storage Agent Push Install Utility.
QoSS (Quality of storage service)	A technique for managing storage resources to fulfill predefined service-level criteria. For each service level, or tier, policy rules are used to ensure the appropriate level of availability and performance. Also called storage tiering.
qtree	In NetApp unified storage devices, special subdirectory of the root of a volume that acts as a virtual subvolume with special attributes.
RAID	Redundant Array of Independent Disks. A set of techniques for managing multiple disks for cost, data availability, and performance. See also mirroring or striping.
rank	A storage virtualization object created from one or more IBM DS6000 or DS8000 storage arrays. The storage in ranks can be organized into extent pools. See also extent pool storage array.
raw device mapping (RDM)	A virtual disk that has a LUN directly assigned to its virtual machine without the layer of a storage pool. In this situation, the LUN is fully dedicated to the virtual machine. Additionally, the virtual disk and LUN have a one-to-one mapping.
rediscover	An operation in which up-to-date status information about managed resources is sent to the Management Server. The rediscover operation, which a CommandCentral Storage operator can initiate through the Console, can be performed for a single resource, for a device manager, or for an explorer.
resource	Any of the individual components that work together to provide services on a network. A resource may be a physical component such as a storage array or a switch, a software component such as Oracle8i or a Web server, or a configuration component such as an IP address or mounted file system.
resource type	A way of classifying resources in a cluster. Each resource is identified by its name and its resource type. Veritas Cluster Server includes a set of predefined resource types for storage, networking, and application services.
robotic library	A collection of tapes controlled and managed through firmware.
router	A device that connects two segments of a storage network and determines the optimal path along which traffic should be forwarded. Also gateway. See also bridge

SAN (storage area network)	A network linking servers or workstations to devices, typically over Fibre Channel, a versatile, high-speed transport. The storage area network (SAN) model places storage on its own dedicated network, removing data storage from both the server-to-disk SCSI bus and the main user network. The SAN includes one or more hosts that provide a point of interface with LAN users, as well as (in the case of large SANs) one or more fabric switches and SAN hubs to accommodate a large number of storage devices.
scan	An operation that detects all resources visible to an explorer through either an in-band connection or a device manager. A CommandCentral Storage operator can initiate the scan operation through the Console. A scan is also performed routinely whenever an in-band explorer executes.
SCSI	Small Computer Systems Interface. A hardware interface that allows for the connection of multiple peripheral devices to a single expansion board that plugs into the computer. The interface is widely used to connect personal computers to peripheral devices such as disk and media drives.
SCSI bus	The communication pathway between a SCSI host adapter card and target SCSI devices. Physically, the bus begins at one end of a SCSI cable at the host adapter card and ends at the other end of the cable at the target device.
SCSI disk	A storage device (fixed disk) attached to a SCSI bus.
SCSI LUN	A division within a group of SCSI devices that identifies a sub-device. See also LUN.
SICL (Simple Instrumentation Collection Layer)	An engine, residing on the CommandCentral Storage Standard Agent, that launches scripts and transfers the script output to the Alert Manager. Each SICL script, written for a particular vendor's device, gathers data using native techniques such as vendor CLI, log file scrubbing, and database mining.
slot	An opening in a computer or other network device into which a printed circuit board can be inserted, adding capability to the device. Also expansion slot.
SMTP	Simple Mail Transfer Protocol, a commonly used protocol for sending email messages between servers.
SnapMirror	A method of mirroring volumes and qtrees on NetApp unified storage devices. With SnapMirror, a user can schedule or initiate data transfers, request information about transfers, update a mirror, and manage mirrors. CommandCentral Storage can discover and display information about SnapMirrors. See also mirroring.
snapshot	A point-in-time image of a volume or file system that can be used as a backup.
SNMP	The Simple Network Management Protocol for Internet network management and communications used to promote interoperability. SNMP depends on

cooperating systems that must adhere to a common framework and a common language or protocol.

soft zoning	A fabric zoning method that filters the visibility of objects on the storage network so that an object can only see other objects that share at least one zone membership with it. Unlike hard zoning, soft zoning is not enforced at the switches themselves. See also hard zoning.
Standard Agent	The Standard Agent is a CommandCentral Storage component that assists the Management Server in the discovery of storage resources. Like the Management Server, the Standard Agent includes the explorers that discover information about the hardware and software in your storage network. Before CommandCentral 5.2, the Standard Agent was known as the managed host.
storage area network (SAN)	See SAN
storage array	A collection of disks or tapes that are part of a storage subsystem, managed as a unit by a body of control software. The disks or tapes may be housed in a single physical device or in multiple devices. See also disk array tape device.
storage device	See device.
storage pool	A single entity representing a collection of LUNs. Using storage pools, storage administrators can create virtual disks of different sizes. These virtual disks can then be assigned to virtual machines.
Storage System	A NetApp unified storage device that operates using Data ONTAP software. MultiStore Virtual Systems, also known as Multistore devices, can be configured on physical filers (pfilers). See also NetApp unified storage.
storage view	A logical port defined for an array that supports SMI-S 1.1. When a storage view is defined, the array can support LUN masking with multiple, heterogeneous hosts through a single physical array port. See also array virtual port.
striping	A layout technique that spreads data across several physical disks by mapping the data to successive media, known as stripes, in a cyclic pattern. Also RAID Level 0.
subnet	A portion of a storage network typically consisting of all machines in one locale, in one building, or on the same local area network (LAN). Internet Request for Comments 950 provides the standard procedure for creating and identifying subnets.
subnet mask	A 32-bit mask that identifies the portions of an IP address to be used for locating addresses in a subnetwork.
subscribed capacity	The capacity that is allocated to thin LUNs.
subscription limit	The maximum amount of capacity that can be allocated to thin LUNs.

switch	A network device to which nodes attach and which provides high-speed switching of node connections via link-level addressing.
Symantec Private Branch Exchange (PBX)	A common component that uses socket passing to reduce the number of ports required to be open across a firewall. PBX uses a paradigm similar to that of a telephone switchboard in which calls placed to a switchboard are redirected to a known extension. In the PBX exchange, client connections sent to the exchange's port are redirected to an extension associated with the CommandCentral Storage Management Server.
Symantec Product Authentication Service	A component of Veritas Security Services (VxSS) that is used by CommandCentral Storage to provide user authentication. Authentication Service is a set of processes and runtime libraries that enables users to log on to multiple Veritas products with one login. See also Symantec Product Authorization Service
Symantec Product Authorization Service	A common component, also known as VRTSaz, that provides a centralized access control decision-making service. After the Authentication Service has validated user identities, the Authorization Service makes access control decisions, determining whether specific users have the authority to perform specific tasks on specific resources being protected by authorization. The Hardware Abstraction Layer (HAL) is the only part of CommandCentral Storage to use the Authorization Service, using it to control access for inter-process communication. See also Symantec Product Authentication Service.
system	The physical hardware on which data and applications reside, and the connections between them.
tape device	A storage device that writes data to tape. CommandCentral Storage identifies a tape drive, tape transport, and tape arrays as a tape device.
tape mark	A mark that is recorded between backup images on a tape.
Task Manager	A CommandCentral Storage Management Server component that manages user-initiated requests to requests to change the status or configuration of objects in the network and to add, edit, and delete users. The Task Manager maintains a list of completed, pending, and active tasks. The list can be viewed using the Console Task Status tab.
thin device	A LUN or other device that is part of a thin pool.
thin pool	A storage pool of array LUNs or physical disks from which thin LUNs are carved out.
threshold	A user-defined capacity percentage that triggers an alert when consumption reaches the maximum allowable utilization level.
topology	The physical or logical arrangement of resources on the storage network and the connections between them.

Topology Map	A graphical representation of the physical or logical arrangement of storage resources in the network. The Topology Map depicts both the objects on the network and the connections between them. In CommandCentral Storage, the Topology Map displays on the Console's Topology tab.
unallocated storage	LUNs that have not yet been allocated. A LUN is considered allocated when a host operating system has written a device handle for the LUN (in other words, claimed the LUN) or when the array has masked the LUN to a specific target. Contrast with allocated storage
unclaimed storage	Storage that has been allocated to hosts whose operating systems have not yet written device handles. This is usually wasted storage. Contrast with claimed storage
unconfigured storage	Physical storage that has yet to be formatted. Contrast with configured storage
unidentified adapter	An HBA or storage device that has logged into a Fibre Channel switch and about which CommandCentral Storage has no information. For HBAs, this can occur when the host contains an unsupported HBA or driver version or CommandCentral Storage does not discover the host (for example, through a Standard Agent or agentless discovery). For storage devices, this can occur when no LUNs are visible (usually due to zoning or LUN masking security).
Unified Agent	The Unified Agent is a part of Veritas Storage Foundation. It consists of the VRTSsfmh package, which collects information about a host that includes a Storage Foundation product. Wherever Storage Foundation is installed, CommandCentral can use the agent to discover information about the host.
unified logging	A common logging library used by Symantec products and components to log information about errors and other events. CommandCentral Storage users can manage and view these logs using Symantec common log tools: `hallog`, `vxlogmgr`, `vxlogview`, `vxlogcfg`, and `vxloggen`.
unified storage	See NetApp unified storage
unusable data device	A data device that belongs to a thin pool from which capacity cannot be allocated for thin devices.
unused storage	Storage to which data has not been written. Contrast with used storage
usable data device	A data device that belongs to a thin pool from which capacity can be allocated for thin devices.
used storage	The portion of storage allocated to a file system or database to which data has been written, expressed as a quantity (such as 10 GB). Contrast with unused storage
user-created host	A host that CommandCentral Storage discovers by remotely running scripts that discover information about the host. See also agentless.

VEA (Veritas Enterprise Administrator)	A separate middleware server used by the SAN Access Layer and other processes to provide client-server communication. The VEA infrastructure enables software components to share information about objects, manage those objects, and effect change on those objects.
Veritas Cluster Server (VCS)	An open systems clustering solution that minimizes planned and unplanned downtime, simplifies server consolidation, and allows the effective management of a wide range of applications in multiplatform environments.
Veritas Cluster Server cluster	A cluster consisting of multiple systems connected in various combinations to shared storage devices. Cluster Server monitors and controls applications running in the cluster and can restart applications in response to a variety of hardware or software faults. A cluster is defined as all systems with the same cluster identification and connected via a set of redundant heartbeat networks. Clusters can have from one to 32 member systems, or nodes.
Veritas Cluster Server service group	A set of resources working together to provide application services to clients. For example, a Web application service group might consist of: disk groups on which the Web pages to be served are stored; a volume built in the disk group; a file system using the volume; a database whose table spaces are files and whose rows contain page pointers; the network interface card or cards used to export the Web service; one or more IP addresses associated with the network card(s); the application program and associated code libraries. Cluster Server performs administrative operations on resources, including starting, stopping, restarting, and monitoring at the service group level.
Veritas NetBackup	A Symantec product family that provides a fast, reliable backup and recovery solution for environments ranging from terabytes to petabytes in size. The term NetBackup refers to either of two products that interact with the CommandCentral Storage product: Veritas NetBackup DataCenter and Veritas NetBackup BusinesServer.
Veritas Volume Manager	A Symantec product installed on storage clients that enables management of physical disks as logical devices. Veritas Volume Manager enhances data storage management by controlling space allocation, performance, data availability, device installation, and system monitoring of private and shared systems.
virtual fabric	A storage area network (SAN) technology in which a group of switches and other objects constitute a hardware-based, isolated environment within a physical fabric. Virtual fabrics create multiple, isolated SAN environments within a physical SAN fabric in order to enable more efficient use of the SAN, especially in terms of availability and scalability. Also called virtual SAN or VSAN.
virtual hub	A set of switch ports on the same fabric that are placed into a logical grouping and use an address spoofing mechanism to emulate a Fibre Channel Arbitrated Loop (FC-AL) hub. A virtual hub can be comprised of all the ports on a single switch or several ports on one or more switches. It is used primarily to allow older

loop-only devices to be attached to a switched fabric and be accessible as though they were fabric capable.

virtual IP address	A unique IP address associated with a VCS cluster. This address can be used on any system in the cluster, along with other resources in the VCS cluster service group. A virtual IP address is different from a system's base IP address, which corresponds to the system's host name. See also IP address.
virtual machine	An environment or software container that does not physically exist but is created in another environment. A virtual machine can run its own operating systems and applications as if it were a physical computer.
virtual machine disk	A disk that is created from the storage within a storage pool. Virtual machine disks are assigned to and provide storage for virtual machines.
virtual SAN	See virtual fabric.
virtualization	A method of representing one or more objects, services, or functions as a single abstract entity so that they can be managed or acted on collectively. An example of virtualization is the creation of a virtual fabric from a switch and associated storage resources as a means of controlling access and increasing scalability in the storage network.
virtualization server	A server that hosts multiple virtual machines with the help of a virtualization application, such as VMware. The virtualization server provides virtualization data to the Management Server.
visible storage	Allocated LUNs that are zoned to a host.
VM disk	See volume manager disk
VM type	See volume manager type.
volume	In storage media managed by Veritas Volume Manager, a virtual disk made up of a portion or portions of one or more physical disks and representing an addressable range of disk blocks. It is used by applications such as file systems or databases.
	In an IBM DS6000 or DS8000 array, an addressable unit (LUN) that is created from an extent pool. See also extent pool
	In a NetApp unified storage device, a file system holding user data that is accessible through one or more of the access protocols supported by Data ONTAP, including NFS, CIFS, HTTP, WebDAV, FTP, FCP and iSCSI. Each volume depends on its containing aggregate for all of its physical storage—that is, for all storage in the aggregate's disks and RAID groups. See also aggregate
volume manager	A method of combining the storage capacity of devices, such as LUNs. Volume managers combine the storage capacity of devices into larger virtual partitions. Administrators can resize or move volume managers without interrupting system use. See also Veritas Volume Manager.

volume manager disk	A device (disk) under volume manager control. Volume manager disks are created from the public region of a physical disk that is under volume manager control. Each volume manager disk corresponds to one physical disk.
volume manager type	The brand or manufacturer of the volume manager. See also Veritas Volume Manager.
VRTSaz	See Symantec Product Authorization Service.
VSAN	See virtual fabric.
VxPBX	See Symantec Private Branch Exchange (VxPBX).
Web Engine	See CommandCentral Storage Web Engine.
World Wide Name (WWN)	A registered, 64-bit, unique identifier that is assigned to nodes and ports.
XML (Extensible Markup Language)	A specification developed by the W3C. XML allows designers to create custom tags to enable flexibility in sharing and displaying Web documents.
zone	A named subset of nodes and ports (zone members) on a single fabric. On a SAN, fabrics secure data from unwanted access by restricting the interconnectivity between nodes belonging to different zones.
zone alias	A symbolic name assigned to a device or group of devices on a SAN fabric. By creating a zone alias, you can assign a familiar name to a device, or you can group multiple devices into a single name. A zone alias must be a unique alphanumeric string beginning with an alpha character. The underscore character (_) is allowed, and zone alias names are case sensitive.
zone member	An object (node or port) that belongs to a zone. An object can be a member of more than one zone.
zone membership	For an object (node or port) on a SAN, the state or status of being a member of a specific zone. A zone member can communicate only with other objects that are members of the same zone—in other words, with objects that share at least one zone membership with it.
zone set	A set of zone definitions for a single Fibre Channel fabric. Zone sets are useful for defining and enforcing access restrictions that change, for example, at different times during the day. A zone can belong to more than one zone set; however, only one zone set for a given fabric can be active at one time.
